A white kidney-shaped variety, strong in habit of growth, and for cropping, cooking, and keeping qualities, all that can be desired. **3s.** per peck of 14 lbs.; **10s.** per bushel of 56 lbs.

WEBBS' NEW MOTOR, Main Crop

A grand acquisition for field cultivation or market-gardening purposes, where a heavy yield is required; beautiful cooking quality. **3s. 6d.** per peck of 14 lbs.; **12s.** per bushel of 56 lbs.

WEBBS' NEW INDUSTRY, Main Crop

Of strong and robust constitution, and a wonderfully heavy cropper. The tubers grow to a large size, and keep well. **3s.** per peck of 14 lbs.; **10s.** per bushel of 56 lbs.

For full particulars see Webbs' Spring Catalogue, post free, 1s.

BARR'S SEEDS
FINEST SELECTED STRAINS
OF TESTED GROWTH

BARR'S 21/- COLLECTION
OF
VEGETABLE SEEDS

Will give a constant supply of Vegetables all the year round. The Seeds are all of the *most approved varieties*, and, as will be seen, the utmost liberality has been evinced.

14 pints Peas
4 ,, Broad Beans
1 pint Dwarf French Beans
1 pint Scarlet Runners
1 packet Beet
1 ,, Borecole
3 packets Broccoli
1 packet Brussels Sprouts
3 packets Cabbage
1 packet Colewort
1 ,, Cabbage Savoy
2½ oz. Carrot
2 packets Celery
1 packet Cauliflower
3 oz. Cress
1 packet Cress, American or Winter
2 packets Cucumber
1 packet Endive
4 packets Lettuce
1 packet Leek
1 ,, Melon
4 oz. Mustard
4 packets Onion
1 oz. parsnip
3½ oz. Radish
1 packet Salsafy
1 ,, Scorzonera
4 oz. Spinach
3 oz. Turnip
1 packet Tomato
1 ,, Vegetable Marrow
1 packet Thyme
1 ,, Pot Marjoram
1 ,, Summer Savory
1 ,, Parsley

Other Collections, **12/6, 42/-,** to 105/-.

All Seeds sent Carriage Paid on receipt of remittance.

NOTES OF THE WEEK.

WALL COPINGS.

THERE is usually some amount of discussion at this season of the year on the question of the utility of movable wall copings in the cultivation of the peach, the nectarine, and some other of the hardy fruits that receive the shelter of walls and are especially liable to injury from spring frosts. In the course of these discussions the most diverse views are expressed, some cultivators regarding them as quite unnecessary, while others consider them as essential to the production of abundant crops, and those who have had but little experience must have some difficulty in reconciling the different opinions. Those who are well versed in the practical work of the garden and are in a position to take a broad view of the question at issue experience no such difficulty, as they know perfectly well that the differences in opinion arise chiefly from the diverse character of the conditions that obtain in the various districts; and they know also that the value of the discussions is materially reduced by the failure of those who take part in them to explain the climatic and other conditions that obtain in the district in which they have obtained their experience. In districts specially favourable to the peach and nectarine there can be no manner of doubt that excellent crops may be obtained in most years from trees that receive no other protection than is afforded by two thicknesses of old fish nets suspended in front of them. When on the other hand there is a difficulty in obtaining wellr-ipened wood, or where the trees are exposed to the full effects of the easterly winds, or to a humid atmosphere during the spring months, portable copings will be of immense assistance to the trees. There is no garden in the United Kingdom where a coping projecting from one to two feet from the wall would not be of assistance, but with so much work to be accomplished in proportion to the labour available, the gardener has to forego everything from which a well-marked advantage cannot be derived, therefore copings are seldom employed excepting in cases where they are known to be absolutely necessary, and not always in these. The utility of the coping consists chiefly in its keeping the flowers, leaves, and young fruits dry, and thereby lessening the risk of their being injured by frost, as when dry both foliage and fruits are able to resist the effects of frosts that would seriously injure them when saturated with moisture. Copings of either wood, or wood and glass, will serve the purpose of keeping the trees dry, but the latter are decidedly the best, and with nets or canvas suspended from a wire fixed near the lower edge form as perfect a protection as we can hope to have. The glass copings possess the advantage that while affording the most ample protection they do not deprive the growth at the upper part of the wall of any appreciable amount of light. The length of time the copings should remain in position can only be satisfactorily determined by local conditions. Speaking generally, they should be removed immediately the trees can be fully exposed without risk of injury from frost; but there are gardens in which they may with advantage be allowed to remain throughout the year. Whenever the rainfall is considerably above the average or where the atmosphere is highly charged with humidity the wall copings may be allowed to remain, and in several Irish gardens where peach culture was considered impossible heavy crops are now annually obtained by adopting the simple expedient of leaving the copings over the trees throughout the year, the change having been brought about by the valuable aid rendered by the copings during the autumn when the ripening of the wood is in progress. Equally satisfactory results would undoubtedly follow from the adoption of this practice in many gardens on the western coast of England.

RIPENING OF BULBS.

"H. H. D'.'s" remarks in our last issue with reference to the necessity of bright sunshine for the proper ripening of bulbs are very much to the point, and it is doubtless, as he assumes, "the one great element of success" for many species. We have, indeed, only to glance at the climatal conditions of the native habitats of most of our favourite bulbs to see at once that they are the evolutionary outcome of long, hot, dry seasons, characterised by next to no rainfall at all, and an average daily temperature high enough to parch into nothingness the great bulk of floral vegetation. During those dry seasons the surface of the soil is literally baking hot day after day, and at the depth of a few inches lie the bulbs, probably in rubbly, stony soil, and certainly subjected to a temperature little below that of the surface itself. In this country we cannot provide such conditions, especially as many bulbs flower and complete the rest of their annual cycle of operations long before our hottest season sets in; and obviously when, during the period subsequent to blooming, the leaves have to perform their allotted task of reconstructing a bulb, they do this under serious disadvantages if rain and cloud deprive them even of the already scanty share of sunlight available. They very probably, however, adapt themselves to circumstances to a certain extent by prolonging the period of maturation, which is undoubtedly effected far more quickly on the native hillside, where the burning sun and soil together hasten the work immensely. Nature, indeed, is very prompt in her work in such climates as bulbs affect; and just as rapidly as the ripening is effected and the foliage burnt up by the sunbeams, so, when the rainy period sets in, the reawakening takes place with startling suddenness and a wealth of gorgeous bloom is speedily outspread where but a week or so previously was a dry and arid desert. It is, indeed, curious to contrast in some cases the natural with the artificial conditions of growth. Take our tulips. We prepare the soil most carefully, and in well-made beds hardly a stone will be found—the aim being to give the delicate roots every chance to penetrate the soil. The surface is carefully tilled and levelled, and all is as tidy and trim as possible. If drought prevail water is supplied, &c., &c. Take now another picture. An exposed stony hillside in Asia Minor, the soil, such as it is, a loose, rubbly mass of fragments of rock and general dèbris, here and there a few sparse bushes of some stunted prickly vegetation, and the only trace of man a barely visible foot-track here and there, while the whole is bathed in sunshine and roofed in with azure of the mediterranean purity. But what is that mass of scarlet yonder on the hill flank? A dense bed of tulips in perfection. Crowded together over many square yards of space are hundreds of brilliant blooms. Try to dig some up, and the soil is so hard that the wonder grows upon one how bulbs can possibly be formed under such conditions; and yet the blooms are splendid, and the whole mass transferred to one of our parks would lose nothing, as far as massing and glowing colour are concerned, by comparison with its pampered kinsmen of our most up-to-date catalogues. All this, of course, shows us the wonderful adaptability of plants, but, none the less, is it advisable to study their natural requirements to the utmost, especially as some are not so amenable as others, and some altogether refuse to be revolutionised, and will either have their full share of sunshine, like "H. H. D'.'s" cyclamen, or perish in default.

GARDENERS' ORPHANS.

THE progress made by the Royal Gardeners' Orphan Fund during the ten years that have elapsed since its foundation has been sufficiently substantial to justify the feeling of "pride and satisfaction" to which the executive gave expression in the report presented to the annual meeting held on the 18th inst. The charity, as briefly stated, has become firmly established among the gardening institutions; it has assisted a large number of orphan children, and it has invested a reserve fund, which if not particularly large is sufficient to show that both officers and members of committee have fully appreciated their responsibilities and also the necessity of economy in the administration of the funds. These are matters on which the members have good cause for congratulating themselves, and it is satisfactory to observe that the guardians of the children are grateful for the assistance rendered them, and that several of the horticultural societies have shown how substantial is the aid these associations are able to give to the charity. On the other hand we regret to learn both from the report and balance-sheet that the receipts have not been so satisfactory as could be desired, and more especially is it disappointing that of the income the sum of £349 11s. only was received in the form of subscriptions, this being less than one-half the amount required for the payment of the pensions to the children. The card collection was even less satisfactory, for notwithstanding the large number of cards sent out, the aggregate amount derived from them was £33 plus a few shillings. The amount derived from these sources is wholly inadequate, and indicates that the gardeners of the United Kingdom do not sufficiently appreciate the value of the charity or their responsibilities in the matter. The fund was established in the interest of gardeners, and is carried on solely for their benefit, and with Mr. Sherwood we wish that a feeling of responsibility for the success of the fund would extend more widely amongst gardeners of the United Kingdom. We fear that the majority of gardeners do not appreciate the fact that it is within their power to materially assist in the good work without unduly taxing their resources, with a moderate degree of effort on their part. Very few, we venture to suggest, are so placed that they cannot collect a few shillings, and many might help to augment the list of members; and, as indicating how much may be accomplished in this direction, we would direct attention to the fact that last year fifty-five new subscribers were obtained in the neighbourhood of Southampton by one gardener. This should be sufficient to prove that there is an abundance of fertile soil untilled that, with judicious cultivation, might be made to bear abundantly. Not only is there necessity for increased individual effort; but it is especially desirable that the various societies associated with gardening should assist as far as possible, in the good work, by means of collecting boxes, by flower stalls at their annual exhibitions, or by arranging entertainments. With but little effort on the part of the general body of gardeners and departmental foremen in commercial establishments, the income could be so increased as to admit each year of the whole of the eligible candidates being placed on the pension list and thereby prevent the disappointment that must of necessity have been felt this year by a large proportion of the candidates.

Affairs of N.C.S.—As a complement to the discussion on the question of holding the exhibitions of the National Chrysanthemum Society at the Royal Aquarium, Mr. J. W. Moorman has issued an eight-page pamphlet in which he quotes a number of anonymous writers in support of the views to which he has given expression, in consequence of "the feeling expressed privately by committeemen and others." Committeemen have, of course, a right to express their opinions privately, as have other individuals; but we are fully persuaded that the world at large will not attach much value to the opinions of gentlemen responsible for the government of a great society who indulge in grumbling among their friends instead of submitting to the committee their views on any reforms they may consider desirable, that an opportunity might be afforded for discussing them at the committee table. On the last page of the pamphlet Mr. Moorman asks, What is to be done? and then says that the following suggestions "appear to require ventilating at the annual meeting": (1) Whether the time has not arrived for the society to have a paid secretary and no vote? (2) That it be an instruction to the committee to inquire and report on what other places (if any) can be obtained for our exhibitions, either by a subsidy, as now, or otherwise? (3) To consider if the time has not arrived when in reliance on our own resources we can proceed on independent lines, like most provincial societies which are in a sound financial condition? (4) As there appears to be much disquietude arising from the fact that the secretary is the delegated referee at all our exhibitions, whether the advisability of a change should not be considered in the form of a small Reference Committee or otherwise? (5) That as the custom of selling the floor space of the Aquarium to trade exhibitors (some of whom are not *boná fide* growers of chrysanthemums), and that inasmuch as such sales have driven competitive exhibits of chrysanthemums into semi-dark galleries upstairs, whether such custom of selling space for a different purpose than that for which the National Chrysanthemum Society was established shall be seriously considered with a view to its discontinuance? (6) That an Exhibition Committee be appointed to closely examine the question of minor shows with the object of ascertaining their advantages or otherwise to the society, and report the results of their investigations to the General Committee. Mr. Moorman does not state whether he intends submitting the questions embodied in the suggestions before the members at the annual meeting in the form of resolutions, that they may be properly discussed by the members. They contain much that is deserving of the most careful consideration, and we are in full agreement with him as to the desirability of effecting several of the reforms indicated, and regret they should have been brought forward in a manner that will render it difficult, if not impossible, for them to obtain proper attention.

The Stratford Market, instituted by the Great Eastern Railway Company, has become the immense distributing area of vegetable foods it now is largely owing to the failure of the company to establish a vegetable market at Bishopsgate within the area of the Spitalfields monopoly. Stratford commenced as a hay, straw, and cattle feeding stuffs market, but since 1882 it has enlarged its borders and increased its business in a remarkable manner. In 1881 the traffic to Stratford Market was 9,665 tons, but, owing to the close of Bishopsgate Market the following year, the tonnage rose to 12,549 tons in 1882, this amount including 15,509 tons of potatos, 5,536 of vegetables, 4,797 of cattle feeding stuffs, 1,907 of carrots, and 473 of fruit. Ten years later the tonnage had risen to 38,738 tons, consisting of: Potatos, 24,853 tons; vegetables, 5,990 tons; cattle feeding stuffs, 4,740 tons; carrots, 2,631 tons; and fruit, 524 tons. The market traffic at Stratford in 1897 shows very plainly that fruit culture has increased, and that the demand has also increased for it and other vegetable products even more than the increase ot population would lead one to expect. The figures for 1897 are 30,074 tons of potatos, 12,544 tons of vegetables, 5,691 tons of cattle feeding stuffs, 2,553 tons of carrots, and 1,162 tons of fruit. At first sight these figures are startling, but, if we remember that Stratford is, after all, only one of the distributing centres of vegetables and fruits, and supplies but a small portion of the metropolitan population, we have some idea of the amount of food London needs.

The Ferns of Nicaragua have been investigated by Mr. B. Shimek, and his report is of much interest. The number of species enumerated, including Ophioglossaceæ and Maratticeæ, is one hundred and ninety-eight, belonging to thirty-nine genera, justifying the author's description of Tropical America as the "fern paradise of the earth." The larger number of these were collected by the author in a botanical expedition undertaken for the University of Iowa. The high mountains in close proximity to the sea afford a climate remarkably well adapted for the growth of ferns, which are stated to form the most conspicuous feature of the vegetation excepting palms. A large number are epiphytic, and they vary in size from tiny species of Trichomanes, with fronds only a fraction of an inch in height, to clinging "vines" like Blechnum volubile, single fronds of which often exceed thirty feet in length, or to splendid tree ferns. The paper is illustrated by twenty excellent plates.

Succulent Plants of all kinds are remarkably interesting, and not a few of them, especially the cacti, produce blooms of wondrous beauty; this being so, it is not to be wondered at that a very large number of amateurs make them their special hobby, and cultivate them with considerable skill. So large, however, is the range of species, that many are yet imperfectly understood, both as regards identity and cultural requirements. The outcome of this is the establishment of the *Cactus Journal*, a monthly periodical, published by Mr. Allen, 4, Ave Maria Lane, E.C., and, so far as we are aware, this is the first effort made in this kingdom to establish a journal for cactus specialists, though Germany has long had its *Cactunkunde*. The first number of the *Cactus Journal* contains admirable articles by Mr. W. Watson, Professor Luis Murillo, Dr. Dixon, Mr. F. A. Haage, jun., and others well qualified to contribute to our knowledge of cacti. The illustrations are mostly old friends, but doubtless original ones will be used in future issues. The double-page illustration of two bowls of curious cacti, one containing opuntias and the other mammilarias, is, however, beautifully executed, printed on stout paper, and valuable for purposes of identity. The issue concludes with Exchange columns and offers for sale of duplicate specimens by amateurs. In size it is small quarto, and contains sixteen pages, exclusive of covers. The use of capital initial letters to the specific names is in very many instances erroneous, but this matter can be remedied in the next issue; for, as an authority on succulents generally, and cacti in particular, there should be a useful and profitable future for the *Cactus Journal*.

Palm House for Stanley Park, Liverpool.—On the 23rd inst., Mr. Henry Yates Thompson, of Thingwall Hall, near Liverpool, and of Bryanston Square, London, made arrangements to provide Stanley Park, Liverpool, with a handsome conservatory or palm-house somewhat similar to the handsome structure presented by him to the corporation, and erected in Sefton Park in 1896. It will, however, be a smaller house, as befits the park, and whereas the one at Sefton, together with the plants, cost £12,000, the one at Stanley Park will cost £6,000. Messrs. Mackenzie and Moncur, of Edinburgh, are the designers and builders, and their plans met with the approval of the corporation. It is almost unnecessary to add that the Lord Mayor and Aldermen of Liverpool heartily thanked Mr. Yates-Thompson for his princely gift.

Classification of Chrysanthemums.—At the meeting of the General Committee of the National Chrysanthemum Society on Monday evening, the Classification Committee presented a report of a meeting held a short time since. The committee reported that it had been decided to place the following varieties in the incurved class: Austin Cannell, Ernest Cannell, Lady Isabel, Lyne Junior, M. L. Faure, Madame Ferlat, M. Desblanc, Owen's Crimson, W. Carpenter, Enfant Desblanc, Mrs. N. Molyneux, Harold Wells, and Sir Trevor Lawrence. The Classification Committee also recommended that, with a view to prevent, in the case of varieties possessing a considerable degree of similarity, the staging of duplicates, a regulation should be inserted in the society's schedule to the effect that the blooms staged in classes for distinct varieties must be shown in a condition to admit of their being readily distinguished by the judges, or the stands will be disqualified. The recommendations of the Classification Committee were accepted, and that body was instructed to prepare a list of too-much-alike varieties. As certain varieties at certain stages bear such a close resemblance to each other, it will be necessary for exhibitors, in making up their stands, to select blooms that are sufficiently distinct to prevent any doubt arising as to the question of duplicates. This is a very wholesome rule, and it is much to be desired that chrysanthemum societies generally should adopt it, more particularly those in affiliation with the National Chrysanthemum Society.

Lilium auratum at Oakwood.—In a communication of the 19th inst., directed from Heatherbank, Weybridge Heath, G. F. Wilson, Esq., writes: We have lately dug up at Oakwood some large beds of Lilium auratum, which had not been disturbed for ten years. Many of the lily stems had been browned by a hard frost, late in last May, which lasted all night. We found many fine bulbs, and more small ones made from large bulbs which had broken up. We found also a good many cockchafer grubs, and a greater number of long, white, narrow grubs, which an eminent entomologist tells me "are the grubs of the small Swift Moth (*Hipialus lupulinus*), a destructive beast to anything under ground." After this experience I would advise examining parts of large lily beds every winter, so as to be sure that grubs are not present in quantity.

Mr. Arthur W. Sutton, F.L.S., gave his interesting and instructive lecture upon "Potatos, their Past, Present, and Future," before the Bournemouth Gardeners' Association a few days ago. As usual, Mr. Sutton illustrated his remarks bp excellent lime-light views, and the large meeting did not fail to accord the lecturer its heartiest thanks for his attendance.

Churchyard Bottom Wood.—At the meeting of the London County Council, on Tuesday, the Parks and Open Spaces Committee brought up a favourable report recommending the contribution by the Council of £5,000 towards the fund for the acquisition and laying out of Churchyard Bottom Wood, Highgate, the balance of £30,000 being found by public subscription and the local authorities. Colonel Rotton moved as an amendment that the amount of the proposed contribution should be £2,500. His only objection to the grant was that the Churchyard Bottom Wood was outside the County of London. The amendment having been seconded, Mr. Shaw Lefevre gave his positive assurance that if the larger sum of £5,000 were not granted, and the amendment was agreed to, the whole scheme would fail. The promoters of the scheme had exhausted all possibilities of raising money elsewhere. Mr. Idris said that the people of London would suffer an irrevocable loss if the opportunity of acquiring this large open space was allowed to slip by. The price asked for it was most reasonable, being less than £500 an acre. There were a number of precedents for the proposal of the committee. On a show of hands only five voted for the amendment, and the recommendation to contribute £5,000 was agreed to, with the result that this fine open space would be secured for public use.

The National Poultry Test is, we are pleased to learn, likely to prove successful. Writing from Burbage Hall, Leicestershire, on the 14th inst., Mr. K. B. Bagehot de la Bere says: Many of your readers may be interested to know that some one hundred and fifty landowners, tenant farmers, and others have signified their intention to take part in the national poultry test to which you called attention a short time since; and as these are widely distributed over Great Britain, we may reasonably hope, twelve months hence, to be able conclusively to determine as to whether egg production can or cannot be made a profitable branch of our agricultural industry. Apart from the above test scheme, I shall be pleased to receive a balance-sheet from any poultry-keeper who will keep strict accounts for twelve months commencing March 1 next. These returns should prove interesting as well as instructive, although they cannot be considered of the same value as those which conform to the six test rules. I may mention that considerably over one million copies of the "Poultry Test Circular" have been distributed through the post and Press columns.

Essential Oils of Value are produced by a considerable number of plants indigenous to New South Wales. The oil obtained from the Native Sassafras resembles, in odour, ordinary sassafras oil, with an admixture of oil of caraways, and is used for medicinal purposes. Eucalyptus oil possesses many valuable qualities, and is said to possess the power of destroying bacteria. Its antiseptic powers have been fully recognised by the medical profession, and by many it is preferred to carbolic acid in the treatment of wounds. The leaves of the various kinds of eucalyptus are found useful in preventing or removing scale in boilers. The oil of the Mountain Ash, a common species of eucalyptus, dissolves gutta percha readily, and can be used, like kerosene, for lamps, having a greater illuminating power, a pleasant odour, and absence of liability to explosion. Three ounces of the oil have been found sufficient to scent eight pounds of soap at a cost of one farthing per pound. The oil obtained from the Stringy Bark is found to be more efficacious, in many complaints, than the ordinary English peppermint, being less pungent and more aromatic. The oil of the White Gum has been suggested as a soap perfume. The Woolly Butt oil possesses the remarkable property of imparting an indelible stain to paper, but at present it has not been utilised for commercial or industrial purposes. The oil of the Grey Gum possesses a delicious citronelle odour, and makes an excellent soap perfume. Several varieties of the Tea Tree furnish an oil possessing most, if not all, of the properties of cajuput, so largely used in India as a remedy for rheumatism. Practically, the number of native shrubs and trees in New South Wales capable of being utilised in the manufacture of perfumes and essential oils is without limit, and when the large quantities of either product, obtainable from comparatively small proportions of bark or leaves, is taken into consideration, it will be seen that in this direction New South Wales possesses exceptional advantages for those possessing the requisite capital and experience to establish large and remunerative productive industries. The essential oil of the Red Gum has been found a good remedy for chronic dysentery, and that of the Moreton Bay Ash makes an excellent furniture polish. It may also be mentioned that the olive, castor oil plant, and linseed, grow luxuriantly in the colony, and are easily cultivated.

The Temple Gardens.—Under the Inner Temple Buildings (King's Walk) Bill, which is being introduced to the House of Commons, the Honourable Society of the Inner Temple seeks power to build upon a portion of these gardens. Mr. Basil Holmes, secretary of the Metropolitan Public Gardens Association, in calling attention to the Bill, writes: By the Thames Embankment Act, 1862, the Metropolitan Board of Works was authorised to execute various works, including the Embankment from Westminster Bridge to the eastern boundary of the Inner Temple, and it was provided that all the land reclaimed from the Thames, and lying in front of the then southern boundary of the Temple, should belong to the societies of the Inner and Middle Temples respectively. But the Act also provided that no building should be erected on this reclaimed land other than certain keepers or gardeners' lodges, of one storey only, of which the First Commissioner of Works might approve. The present Bill seeks to give power to the Inner Temple to appropriate for building purposes so much of the reclaimed land as lies between the former southern boundary of the Temple and the District Railway tunnel, with a width of about eighty feet measured westwards from the eastern boundary of the Inner Temple. To this extent the Thames Embankment Act, 1862, would be set aside, if the Bill passes, nor is any provision made for compensation to the public. The frontage land was not created by the Metropolitan Board of Works with money provided by the Inner Temple, and, if the land had been sold for building purposes by the Board it would have realised a large sum, which would have been some set-off against the cost of the Embankment. One would have thought that the land should have been retained by the Board of Works as a public garden in extension of the existing Embankment Gardens. But the very least Parliament could do, in giving the land into the hands of those who can exclude the public therefrom, was to impose a condition that it should always remain as an open space. If Parliament in its wisdom now thinks fit to allow this open space to be built on, then clearly the Inner Temple should be made to buy it at its market price as a building site, and the money so obtained should be devoted to open-space purposes. But I trust that Parliament will definitely decline to allow our noble Embankment to be seriously injured by the formation of a building frontage so close to the public thoroughfare. If this attempt of the Inner Temple to obtain building land on the cheap is successful, it will only be a question of time before they and the Middle Temple secure the remainder of the open space as a most profitable building site without payment, when, of course, the Temple Gardens, which add so much to the beauty of the Embankment, will be much curtailed, and will be shut out from public view.

The Botanical Society of France has elected Mons. Franchet as its president for the ensuing year, and MM. Zeiller, Boudier, Rose, and Clos, as vice-presidents.

Women Gardeners at Swanley.—The annual report of the Women's Branch of the Horticultural College, Swanley, shows that during the year 1896 many of the students have received professional appointments, and altogether there are twenty-eight women, who, after a Swanley training, now hold positions as nead gardeners, horticultural lecturers, &c. Of course, many go to Swanley simply with a view to managing their own establishments subsequently, and not in the hope of gaining professional appointments. Among the college successes it is pointed out that Miss Gulvin, one of the students first employed at Kew, has now undertaken a responsible post with several gardeners under her, among whom is Miss Groome, also from Swanley. Miss Hutchings remains at Kew, and is now a regular gardener on the staff. Two others are also now in training. Two students are at the Royal Botanic Gardens, Edinburgh. Miss Smith is still at Lady Henry Somerset's industrial farm colony ar Duxhurst, where she organises and directs all the horticultural work. Miss Prior is directing and instructing in gardening the patients of the convalescent home at Hale. Miss Agar is employed by Miss Dove at the Wycombe Abbey School as head gardener and teacher of practical gardening. Miss Clark has been teaching botany at the Princess Helena College, Ealing Miss Morison has been employed by Miss Wilkinson in the laying out of gardens in London under the Metropolitan Public Gardens Association. Miss Atkey has been employed by Mrs. Garrett-Anderson, M.D., in planting and laying out an orchard in Suffolk. Miss Windermer and Miss Cope have been appointed to lecture on beekeeping and on London trees respectively.

National Chrysanthemum Society.—A meeting of the General Committee was held on Monday evening, and, in consequence of the length of the agenda paper, the members were busily engaged for upwards of three hours. Among the numerous items on the agenda were the annual report and the balance-sheet, which are, as usual, of a satisfactory character.

THE PRUNING OF ROSES.

LOOKING through many beds and borders of roses at the close of last week it was impossible to note their vigorous growths, ranging from two to six inches, without an uneasy feeling of fear for the safety of our fast-growing and dangerously early budding roses.

Some growers advocate early and close pruning as their antidote to early growth. A long lifetime of watchful experience among the roses lends no support to the theory or practice of early pruning as a mode of modifying or preventing the evils and dangers of early growth; so long as we can retain plentiful reserves of dormant buds our rose harvest is tolerably safe.

With all the abnormal warmth of a hitherto winterless winter summoning our roses into vigorous growth, they will—they must grow—prune then when or how we may.

It must be admitted that the buds on the extremities of the shoots burst or break into growth first. The old rosarians used to say that was because they were nearer to the sun, and therefore the first to see and feel his quickening power Be that as it may, the upper buds still break first, and, in breaking, these growing buds blow off as well vital force or steam from the lower ones, and in doing so hold the late roses back for the enrichment of our gardens—or the furnishing of our rose shows. So that rosarians gain infinitely more by allowing the top ends to run to waste than by pruning them back to the dormant buds in winter or early spring. I do not say that winter pruning may not lessen the volume, or modify or put back the time, of the dangerous flood-time of spring sap in our roses. No, close winter or spring pruning does both in degree and to a certain extent. But it is abundantly proved that it creates new dangers of more far-reaching import to rosarians. We all admit that the abnormal and premature growth of our roses, in January and February especially, is attended with many serious risks and dangers. We can also, in a certain measure, afford to be almost indifferent to the loss of many top buds on our rose shoots. But ultimate results often prove to rosarians that these do not suffer alone. It is as true of roses as of our own bodies, if one member suffers other members suffer with it. It is not needful to carry the analogy too far, nor to run it too closely to feel or see its truth among our roses. Those who can vividly recall their losses among the roses will all too readily remember how unexpected or inscrutable many of the worst of them seemed. Were a zero frost to hit our roses now, we should all be prepared to find our growing branches as black as our hats. But the unexpected often happens among roses. It is when the severities of winter, and the sudden and erratic changes of our volatile springs are over and gone, that our roses begin to droop and die. There may be many causes for this, but I believe one of the most powerful is winter and early spring pruning. This calls up the reserve buds at the base of our roses into premature action or growth, which exposes the very citadel of their life to the killing grip of the frost. The growth of the top buds may not greatly affect the reserve buds at their base; but if too long continued even the base buds may be reached by a process of exhaustion, and the whole plant be rendered abnormally tender through unseasonable excitement. We have but one mode of preventing the consequences of such unnatural conditions—that is by preserving a masterly inactivity with the knife among the roses until the chief dangers from spring frosts are over, and the time for safe growth has come. Then in many cases it may be found little or no pruning will be needed. We will only have to cut back to the best dormant bud, or cut out any weakly wood. Neither have these early shoots been wasted. Already they have served three useful purposes—they have reserved a stock of semi-dormant buds at the base of the shoots, afforded considerable shade or protection to the same, and quickened the roots into abnormal vigour and activity for the supply of all the wants of the coming rose season.

D. T. FISH.

PRIMULAS AT PERRY HILL.

AMONG the several firms of seedsmen and nurserymen that have taken especial pains to improve the garden forms of Primula sinensis, and to create new ones, Messrs. J. Carter and Co., High Holborn, take a foremost place. Grouped under the title of Holborn Primulas, the various improvements instituted and carried out by this firm have been most popular during the past quarter of a century, for not only have fine habit and floriferousness been obtained in a marked degree, but the distinctness and diversity of the colouring now to be found is even more remarkable. To see the Holborn Primulas in quantity and in prime condition, it is neither necessary nor advisable to go to the headquarters of the firm at Holborn, but to the nursery at Perry Hill, about a mile from Forest Hill Station, where away from the dust and smoke of the great city, good light and pure air combine with skilful cultivation to produce a sight, or series of sights, worth going a long way to see. Disregarding for the moment the big lithographed invitation to use Carter's Breakfast Oats, the visitor passes into the nursery and comes quickly upon a number of long span-roofed houses with sunk paths, low-pitched roofs, and broad panes of glass. Even at the present season there is a grand display, although the flowers are being carefully pollenised to ensure a good crop of seed to meet the large demand. In one house there are about a couple of dozen plants of each variety of primula sent out by the Messrs. Carter and Co., so that an ample opportunity is afforded of comparing them with each other, and noting the harmonies or contrasts produced by the several forms. As a rule, however, the primulas are in big batches, seven thousand plants in all, and naturally are most effective seen thus.

The first variety we are invited to inspect is Elaine, a handsome and exceptionally neat primula with bold trusses of neat white flowers, prettily fringed, and carried well above the dark-stemmed foliage; in habit it is everything one could wish, and forms a fine companion for the celebrated Holborn Blue. The latter produces full central trusses surrounded by lesser ones, and forming together a pyramid of flowers; the blooms, charmingly frilled and fringed, are of large size, and of a bright shade of heliotrope blue with vivid blue margins to the bases of the segments. A lovely primula is Princess May, its clear and delicate blush-tinted flowers measuring as much as two and a quarter inches across; it is one of the most handsome of the many varieties here, and is robust in habit. A most attractive primula is Holborn Queen, for its elegant fern-like foliage surrounding the sturdy trusses of white blooms make it a perfect picture; the palest possible pinky blush suffuses the flowers after they have been expanded a few days, but this only adds to the beauty of the variety. The large batches of Holborn Queen seen at Perry Hill arrest the attention of all visitors, and remind us that much seed is required, as the variety is a very popular one. Magenta is a colour that does not find favour in many circles nowadays, but if the dyers were to copy the tint seen in Carter's Magenta primula, it would not fail to become popular; the shade is rather that formerly understood as royal purple, and one which shows up grandly under artificial light; the dark orange eye in this primula is immediately surrounded by a ring of pale rose, and altogether the variety is one of great beauty and usefulness. Holborn Carmine next demands attention by reason of its strength and robust habit; the giant blooms are wonderfully frilled, and of a most intense and telling shade of carmine.

In another structure is a batch of Rose Queen, a variety that for want of a better description may be described as a miniature form of Princess May. Two of the most striking primulas here seen are Holborn Scarlet and Holborn Vermilion; the former, seen in quantity and flowered most freely, reminds one of a regiment of grenadiers in their scarlet tunics, for the colour is as vivid. For grouping this is a famous primula, and the colour is one that we have none too much of among winter flowers. Holborn Vermilion has rather more crimson in it than one would expect from the title, and perhaps the shade would be more aptly described as vermilion-crimson. Ruby is a primula everyone should grow, because it combines in itself all the attributes of a first-rate variety; it is strong in habit, has elegant fern-like foliage, large full trusses, and big frilled blooms; the colour also is very fine and well described as ruby, while the eye is rich orange. Somewhat later than the majority is Holborn Rose, and a splendid batch, consisting of many hundreds of neat plants in forty-eights, is now in the best possible condition; a score or two of such specimens would be just the material for association with the forced bulbs, &c., in a conservatory at the present date. It is a variety with long ferny leafage surrounding large pyramidal bouquets of exquisitely frilled and rich rose-coloured flowers. Holborn Salmon is charming in bulk, profuse in flowering, and most distinct. Like Elaine, Venus is represented by both plain and fern-leaved forms; it is a curious variety having white flowers, flaked with carmine, rose, and purple; owing to its free habit it is highly recommendable to those who like bizarre flowers.

Quite as much in the double and semi-double varieties as in the single forms is continued improvement evidenced in Messrs. J. Carter and Co.'s strains of primulas. The value of double and semi-double primulas cannot well be overestimated, for the flowers are suitable for cutting, and, as they last a good while in a fresh condition, they are available during winter for a variety of uses, and at a period when the demand is great and the supply somewhat restricted. Formerly we had to rely on the double white primula, and propagate it by cuttings or division; now, however, we may obtain useful plants easily from seed, and in at least half-a-dozen different colours. At Perry Hill you may see carmine, salmon, rose, lilac, white, white flaked with rose, scarlet, and blue, in double form, though not all these are yet in commerce. Carmine Empress gives a new shade among double primulas, and is a variety useful alike for the provision of flowers for cutting or for conservatory decoration. It has plain, neat foliage and dark stems. Double Blue is being improved, and will doubtless ere long be more double than at present; the colour is pale blue, and the blooms are prettily fimbriated. Prince of Wales produces flowers with the greatest freedom. It is dwarf and has dark stems; the flowers are rich rose in colour, shaded with carmine, a combination that cannot fail to please. Having a prince, it was also natural for the firm to provide also a princess, so one variety has been named Princess of Wales; it has white flowers prettily flaked with carmine. The pure white double form is properly named Snowflake, for the flowers are pure white, and of large size. Very distinct is Lilac Queen, and the variety is as free as it is distinct. Vivid, a new and brilliant scarlet-shaded carmine variety, will soon have a recognised and high position among the double varieties. Aurora appeals to those who like delicate shades, for it has large flesh-tinted flowers of great beauty and substance. Double Scarlet is remarkable for its compact habit, combined with freedom of flowering and deep scarlet blooms. As a market plant this should prove a great success. Such an advance in double primulas, as these remarks indicate, has not been made in one or two seasons, nor is the firm resting on its laurels now. There are evidences at Perry Hill that careful improvement and selection towards certain ends are still the order of the day, and that more surprises are yet in store.

To give some idea of what may be expected in due course from Messrs. J. Carter and Co., we will briefly refer to two or three successes achieved but not yet distributed owing to the small amount of stock. A variety named Bouquet takes leading place, and is so named because the large central truss has a leafy involucre that serves to set off the white flowers like the fringe of fern in a bouquet. It is a giant form, the immense flowers being heavily frilled; the side trusses are suppressed as such, and in their place a huge flower is produced encircled with a foliaceous calyx. A number of these large flowers surround the central truss, and the individuals composing the latter are also provided with a leafy calyx. It is a handsome and interesting variety, and even when not flowering the frilled lobes of the leaves give the plants an effective appearance. Up to the present Bouquet is very shy of seeding, so that stock is not soon increased. Ere long we may expect a new single crimson variety with very fine flowers of a rich blood-red hue; when it appears it will be likely to supersede the popular Holborn Vermilion, whose child it is. The name of Hercules has been given to a very rich, rose-coloured variety that is exceptionally robust, and produces blooms of astonishing size. These three make up a good new set, and show a marked advance in primula production. We may add that a magnificent lot of cinerarias occupy several houses at Perry Hill; the specimens are especially robust and clean, and a few have expanded their earliest blooms, giving a foretaste of the display that will occur about five weeks hence.

THE BLACK CURRANT MITE.

I FEAR Mr. Berry, the Kentish fruit grower who made such an earnest appeal for scientific aid to help stamp out the black currant mite at the recent annual meeting of the Royal Horticultural Society, and afterwards, as reported at page 10[illegible], brought the matter before the Scientific Committee with, it seems, such indifferent results, must have returned home greatly disappointed. Great as may be the knowledge entomological of members of the scientific body, yet even their capacity to indicate *bonâ fide* remedies is not infrequently limited. Also, it has often happened that the unscientific cultivator is more successful, because of constant and keen observation in suggesting or finding remedies, than are actual scientists. The latter, it is true, do materially help to furnish information with respect to the life history of the various insects or fungoid pests, but, as in the case of the currant mite, be quite unable to suggest any practical remedy. When the only suggestion is entire destruction by burning of all infested bushes, we have to realise that that is not a sensible remedy at the best. It may check the ravages of the mite by absolutely destroying the currant bushes on which they feed, but that would furnish poor relief to the distressed cultivator; and yet we see this pest increasing so rapidly everywhere, that there is grave danger, if the bushes be not destroyed by fire and the mites with them, the insects will practically destroy them by rendering them useless. Of course, it may be said that when a breadth of bushes is attacked by the insect, why not destroy it absolutely, and obtain young bushes from a clean stock, and plant in fresh ground. But what guarantee has anyone that an absolutely clean stock anywhere exists, or that even if found it would remain clean for any period? Because the insect is of such minute form, and growers are not microscopists, there is on the whole very little discernment of the presence of the mite or of its evil effect until great mischief has been accomplished. Probably it would be very difficult to find black currant bushes anywhere a few years old that are not more or less infested with the insect. It does not seem as if the hard and well-armoured buds of the red currant were permeable by the insect. But then, at what stage of growth are the eggs deposited? One fruit authority tells us that they are so deposited in February and in August, but how or by what description of insect little information is afforded.

The same writer also intimates that besides picking off infested buds or cutting away infested shoots, and burning them, remedies found now to be quite ineffective, "no mite can withstand sulphur, particularly bisulphide of calcium, or soft soap, sulphur, and soda wash. Syringe the bushes thoroughly after the fruit is gathered with bisulphide of calcium, clear away the leaves as soon as fallen, and in dry weather again syringe the bushes with the mixture, repeating in February. The soft soap mixture may be used as a spray in November and February. Now the question to be asked is, Have these remedies been tried, and if so have they been successful? Syringing several acres of bushes thoroughly would be a very long and expensive process, especially if done three times. Yet it is difficult to see how any syringings or dressings applied after the buds have hardened and the mites are well enclosed within the bud scales can reach them or be effective. Spider and aphis are invariably amenable to external applications, but the mite is as though protected by an armoured barbette, and is invulnerable to external dressings. As to what effect would be produced on currant leafage by an application of bisulphide of calcium nothing seems to be known. Is it possible for the hybridist to render the black currant grower any assistance by intercrossing the black and the red currant, or with the flowering Ribes sanguinea, bushes of which sometimes fruit freely? At present growers are in a very helpless case, and they need assistance of a very practical kind. The Agricultural Department can muzzle dogs, but the currant mite defies even Miss Ormerod's prescience, and will not be muzzled; and if scientists, departments, and colleges fail to furnish aid in the matter, where is the poor grower to look for it?

A. D.

ISLE OF WIGHT.

THE monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. Mr. J. H. Perkin, [illegible] Sandown, presided over a large attendance of members, in the absence of the chairman, Dr. J. Groves, B.A., J.P., who, however, arrived later in the evening. Mr. J. Hygate, The Briary Gardens, Cowes, gave a thoroughly practical address on "The Cultivation of Grapes in a Cool House," dealing with every phase of vine culture. The subsequent discussion proved interesting and instructive, and was entered into by Dr. Groves, and Messrs. T. W. Butler, A. W. Kime, [illegible] Martin, T. Brown, W. Matthews, J. H. Perkin, and S. Heaton. [illegible] mildew—its cause and cure, received considerable attention, as did also [illegible] growing in the Garden Isle for wine-making purposes. It is believed by [illegible] that there are places in the island where the undertaking would prove a [illegible] financially. The exhibits staged consisted of a collection of cyclamen [illegible] primulas from Mr. H. Drover, Ventnor; a specimen cyclamen, over [illegible] through and with eighty blooms on it, from Mr. A. J. Cole, [illegible] Gardens, Sandown; and a specimen Dendrobium Hilli, with six spikes, [illegible] Mr. Honeybourne, gardener to Lady Daly, Ryde. The exhibits in each [illegible] well merited the association certificate for cultural merit, which they [illegible] on the recommendation of the judges—Messrs. Kime, Butler, Martin, [illegible] and Witty. At the close fourteen new members were elected. At the [illegible] meeting Mr. J. Perkin will read a paper on "Asparagus Culture."

LEAVES FROM A RAMBLER'S NOTEBOOK.

TRUE GARDENERS.

GARDENERS spring up like mushrooms and you meet with them everywhere. In the sense of which I speak of gardeners I do not necessarily refer alone to men who follow the gentle art as a means of obtaining a livelihood, though they are numerous enough, but rather would I include all who have a natural bent for horticulture. Here we have a wide field before us, for true gardeners are to be found among all sorts and conditions of men. Commence high, if you like, among dukes, lords, and baronets, and familiar names rise spontaneously to the lips—names so well known that there is no need to mention them here, and the owners of them are gardeners in the truest sense, because they are endowed with an ardent love for Nature and her capricious workings. Then turn to the professions—the Church, the law, and medicine, and you will find gardeners. Some of them famous in the annals of horticulture, and others following their bent in obscurity so far as the world is concerned, yet obtaining that enjoyment out of the occupation that only a true gardener can. Come lower still, among the working ranks of our great population, and here you find gardeners on every hand. Some are clerks, others artizans, others again labourers, and, in fact, comprising all walks of life that demand the exercise of brain or the energy of muscle; yet they are all gardeners, because Nature made them such, and endowed them with the happy faculty for obtaining pleasure and recreation in studying the gentle art that refreshes wearied brains and makes a pleasant change for those whose main occupation is monotonous and uninteresting.

Perhaps we are to blame for putting such a narrow limit to this world of horticulture, as in the sense that the word is generally understood gardeners are only men to whom gardening is a means of living. All others are classed under the pet name "Amateurs," though they comprise many to whom the appellation, as it is understood, does not apply. In cricket a professional is a man who receives payment for playing, and an amateur is a man who does not. In horticulture the amateur is frequently understood to be only a novice who dabbles a little in gardening for a hobby, and plays at it, so to speak, but surely this is a wrong construction to put upon a community. There are many, of course, to whom the word in this sense justly applies; but on the other hand, there are many more who are amateurs correctly speaking, because they receive no financial remuneration from horticulture, but apart from that they are gardeners, true gardeners, thoroughly understanding the branch they follow, and often able to teach something to men of the professional class. Even among the working population such men are to be found, and in almost every village you will find a section of thorough gardeners. These are the shining lights of the little horticultural world in which they live and are looked upon as authorities. Their allotments and gardens are always a credit to them, and in healthy competition at the village show they vie with each other for the coveted awards. Gardening is their pet theme, and in the spring and summer seasons, after a hard day's work, you may meet with them—a kind of mutual improvement society, studying each other's work, and criticising or approving, as the case may be. You can call such men amateurs if you like; but if so, let it be in the broad sense of the word that also includes them as gardeners who know how work should be done and take a pride in doing it.

Everyone is not acquainted with the difficulties under which some of these men pursue their hobbies, and, as an instance of this, it was my lot last summer to meet with a blind gardener. It was a sad case—a strong, able-bodied man, afflicted in the prime of life through a lamentable accident which robbed him of the light of his eyes. Life was dark to him after that in more ways than one, and, without the faculty of sight, there seemed nothing to live for. He was only a labourer, with labourer's means, and his store of knowledge was therefore small. To use his own words, life seemed a burden, and a sightless existence unbearable. Then something came to the rescue, and that something was his garden—a twenty-rod plot in an allotment field. He found that when sight failed his sense of touch improved, and though his blind orbs were useless, his power of imagination was such that he could see his garden plot in his mind's eye before him. These powers of touch and imagination gradually increased, and wedded him still closer to his garden, which became not only his occupation, but his friend, his companion, and chief solace. The plot would have been a credit to any man, but to one without sight it was much more. It was a picture of order and neatness, every line being perfectly straight and parallel with the next. Interesting, yet painful, was it to watch the patience of the man in measuring the distances, and laying his line for the rows. The times he went over the ground were enough to tire anyone, yet with him it appeared to be a labour of love. Not a weed was to be seen, yet the blind gardener's only means of finding the obnoxious vegetation was by his sense of touch; still, he never by any chance pulled up a plant of the legitimate crop by mistake. He ran the hoe between his rows of growing vegetables with remarkable accuracy that would have been a lesson to many who have a knack of cutting off the plants in this operation. Standing at one end of the allotment, he told me the exact position of every crop, and whether it was doing well or otherwise. He knew when cabbages should be cut, peas gathered, potatos dug, and all the rest of it as well as any professional. He detailed the labour he had with watering, and, turning his face towards the breeze, prophesied rain. He could in imagination see his garden before him, and there lay the light of his darkened life. As I took his hand in sympathy at parting, he turned towards his plot and said, "It's my greatest pleasure in this world; but I shall *see* in the next."

Another individual, whom I shall class as a true gardener, resides—or did eighteen months ago—in anything but an aristocratic part of the thriving Welsh seaport of Cardiff. Hodge's Yard, Bute Docks, does not strike one as being a very salubrious spot, and the name is by no means contradictory to the locality, for it is the last place in which one would naturally look with the idea of finding a gardener. Hodge's Yard is a cluster of little old-fashioned tenements, that probably existed before many of the fine buildings of which Cardiff boasts were thought of. The houses, in fact, by their appearance and situation, might have been washed up there by the tide, and, having found natural moorings, allowed to remain. The murky waters of the docks come nearly up to the doors, and great baulks of timber and barges of coal, iron, and other merchandise appear tc be the only craft that find their way up to the coal sidings, timber yards, and warehouses. On a summer day the aroma from the half stagnant water is not the most pleasant, and the whole surroundings give you the idea of prosperity in one respect, and hard, ceaseless toil, with meagre house accommodation in another. Yet here, under circumstances that many a professional gardener would consider impossible, a man rode his favourite hobby with a success that would have attracted much notice had the conditions been of the most favourable character.

I made the acquaintance of the man, whose name slips my memory, in one of the tents at the Cardiff summer show. From his appearance he might have been anything from a ship's stoker upwards, though I learnt afterwards that he followed the calling of a shoemaker. It was evident the man was in trouble, as he looked in a half-interested manner at a group of specimen fuchsias, and the cause of his discomfiture was that he was a fuchsia grower in a small way, and a prize-winner at previous shows, but on this occasion schedule regulations prohibited him from showing on account of his plants being in too large pots. Expressions of sympathy led to an invitation to pay a visit to Hodge's Yard, and it was not without difficulty that the establishment of my newly-made acquaintance was found. The policemen did not seem to know the exact spot, as Bute Docks covers a wide area, and in Cardiff Hodge's Yard is not so well known as Piccadilly is in London. The fuchsia grower, however, was not without a reputation in his own locality, for on meeting a passer-by, and mentioning the name of the man whom I was looking for, he said, "Do you mean the man who grows fuchsias?" On receiving a reply in the affirmative, he kindly volunteered to act as guide, and short cuts through labyrinths of narrow streets and by dangerous-looking dock cuttings led us to the yard. The appearance of a stranger seemed to excite interest, for groups of grimy-looking youngsters stopped their play and stared as we passed, and then by mutual consent followed in a body, evidently thinking that something exciting was going to take place. Women, too, seemed no less interested, as heads and shoulders appeared at the low doorways, and then retreated or moved a yard or two lower down for an exchange of opinion with the next door neighbour as to the curious phenomenon of a stranger by his presence disturbing the peace of Hodge's Yard.

In the little square of garden which lay in front of the shoemaker's establishment was the greenhouse. It was a curious piece of architecture of various elevations, and appeared to be an ingenious mixture of window frames, and garden lights transformed into a greenhouse. There was no doubt about it being home-made, and apparently the irregularity in outline was due to the addition of wings to the first structure. A couple of downward steps led to the doorway, which was made to be entered in a stooping posture, but once inside there could be nothing but admiration for the contents. There, in that primitive greenhouse and amid the most ungenial surroundings, were specimen fuchsias worth going a long way to see—plants seven and eight feet high, pyramidal in form and clothed from base to apex with healthy foliage and a wealth of handsome flowers. They would have elicited expressions of admiration at a Temple show—yet grown by a mender of boots and shoes. On shelves near to the glass were zonal pelargoniums in pots staked out as specimens, and trained in the most orthodox manner. To examine these closely it was necessary to climb up a step-ladder and look at them from the outside. There was a family interest in the greenhouse, as the shoemaker's wife, in the absence of her better half, told how they had raised, grown and tended the plants, while two or three of the juvenile members were busy on their hands and knees watering the fuchsias. They had won honours, too, and it was with pride that the good woman displayed the medal awarded by the Cardiff Horticultural Society. It would serve no purpose to detail the methods of cultivation as given by the shoemaker's wife, but the splendid appearance of the plants was evidence that it was correct. "He spends most of his spare time with 'em," she said, "and I help him."

I did not attempt to gather the amount of pleasure this shoemaker obtained from his hobby, as, judging from the interest showed by his wife, the conclusion was foregone. At any rate, such a man is a true gardener and worthy of encouragement.

These are but two solitary instances where horticulture brings pleasure to those whose lot is not cast in the easiest walks of life. There is no need to go out to the highways and hedges to find many more. They are here in the midst of us, and daily we are brought into contact with men of all classes who are real gardeners because Nature has made them such; and one asks, Why do so many miss their vocations? for would not such men ornament the calling better than many who are really in the ranks? H.

New Potato, Carter's Snowball.—Carter's Snowball is one of the best new potatos that has come under my notice for some years past; it is a good cropper, and has first-class cooking properties; it does not produce of much haulm as some varieties, but the tubers are quite large enough, nearly round, and very handsome.—JOHN APLIN, *Hasfield Court.*

VEGETABLES FOR EXHIBITION.

MUSHROOMS.

THE cultivation of the mushroom (*Agaricus campestris*) is not nearly so extensively carried on in this country as it deserves to be, and the very large quantities that are annually imported from France and other sources, and the ready sale they always find, will bear this out. If farmers and others who can easily obtain fresh horse-droppings would turn their attention to the culture of mushrooms very large profits, I am certain, could be made. When once their culture is understood the care, trouble, and expense necessary for producing good crops is small compared with the handsome returns that might be made. It should also be borne in mind that the manure is not exhausted on this crop, for old mushroom beds are simply invaluable for kitchen garden crops and many other purposes. Neither is it at all necessary to build expensive mushroom houses. Indeed, oftentimes the best results are obtained in old, disused buildings, or even when the beds are made up (if properly done) entirely in the open. But in my opinion the ideal place for cultivating the mushroom is in caves or cellars underground. Here the temperature is generally suitable, and pretty uniform all through the year.

Outdoor Culture.

We will first deal with mushroom culture in the open. In the first place, it is absolutely necessary to obtain a good supply of fresh stable-manure, which should be collected, as far as possible, at one and the same time, so that the whole may be prepared together. The longest of the litter only should be removed, as short manure is most beneficial in making up outdoor beds and should invariably be employed with the droppings as they remain in a bearing condition for a much longer period when it is used. The next important step is to select a suitable place for drying and preparing the material for bedding, and this should be an open shed. Of course the size of the beds must be determined by the quantity of material at command, but it is far better to make up the bed at different stages than to wait for a large accumulation, as much of the value of the manure will be lost. London horse manure, when it can be depended on, will do well; but the purpose for which it is required should be distinctly stated, and it should be sent clear of other refuse and as fresh and dry as possible. As a rule nothing will be required to be taken from this, as little straw is wasted in London. If sent by trucks on rail no time should be lost in carting it away and placing it in the drying shed. It should be put in a long bed from two to three feet in depth, and turned with forks every other morning for the first ten days, working the outsides towards the middle each time. After this the manure will have lost its rankness, when it may be turned less frequently and put together in a smaller compass. Every third or fourth day will be sufficient for turning. As soon as the heat is well on the decline, and the whole has been sweetened, the manure may be wheeled out and permanent beds formed. The site will, of course, have been fixed upon, and it may be mentioned that almost any place and aspect will be suitable, providing the ground is in such a position that the water does not stand about the beds. This can easily be prevented by raising the ground where the bed is to be made above the natural level. When beds are required to produce mushrooms during the hottest part of the summer choose, if possible, a shady position under a north wall. The beds should be formed ridge-shaped, the base being from four to five feet wide, sloping off neatly to a ridge. It is of the utmost importance that the manure be put together as firmly as it is possible to make it, first by treading and then by beating with wooden rammers as the building-up proceeds. This applies to all mushroom beds, whether under cover or in the open. The beds must not be spawned until in a fit state. To ascertain this, sticks should be thrust into them in several places, and examined every day to see that the heat is declining before the bed is spawned; a safe temperature is about 80 degrees, and by using a plunge-bed thermometer accuracy in this respect may be ensured.

Care should be taken in selecting a supply of good fresh spawn from a reliable source, or otherwise it will be useless to expect a crop of mushrooms. Experience will soon enable the grower to judge of the quality by inspection of the cakes. This should be broken up carefully with the hand to the size of chickens' eggs, and during hot dry weather it is a good practice to dip the spawn in warm water before insertion. All being ready, holes should be made with the hand regularly all over the beds at a distance of nine inches apart and three inches deep. Insert the spawn, and cover in with the manure taken from the holes, which should be pressed back firmly. Many people practise soiling the beds at this period, but it is best deferred for a week, as the temperature of the manure may be increased thereby, in which case another spawning must be made. A thin covering of long stable litter should be placed over the bed for a week. The spawn should be examined in one or two places; if the white thread-like mycelium is spreading, then all is well, and one may look forward with confidence to good results. If, on the other hand, these are stationary and grown black, something is wrong. The question of soil will next arise, and though almost any kind will do, yet by far the best is turfy loam that has been stacked from an old pasture six to twelve months. This should be broken up and passed through a half-inch sieve, rubbing as much fibre through as possible. A thickness of about two inches should be placed all over the bed, and then be sprinkled with warm water through a fine-rosed watering-pot, firmly patting it over with the back of a bright spade. Again cover with a good thickness of stable litter, the thickness being determined by the state of the weather—frost and cold winds must always be excluded. It will depend much on the season as to the length of time it will take to produce a crop; for instance, if the beds are spawned in November, very seldom will the mushrooms be produced before March or April, but beds have been made and spawned at that time of year, which have continued to bear continually through the summer months. The old litter should be removed about every three weeks and fresh added. When gathering the crop always carefully twist the mushrooms, taking them clean out, never cutting them with a knife, as is sometimes done. The beds should be sprinkled daily in dry weather with tepid water, and occasionally given a good soaking with liquid manure from the farmyard.

Indoor Culture.

As before mentioned, caves, cellars, or any such suitable places underground form the best possible mushroom houses, and one can hardly fail if the manure is properly prepared and good spawn secured. The bed here should be made flat, to a thickness of about two feet six inches, spawned and soiled as before advised, when no other attention will be needed, except to damp them over when necessary, and to supply liquid manure now and then when the beds are in full bearing. Mushroom houses are often constructed, and good results in many cases follow. On the other hand, I have seen expensive structures give very poor returns which may be easily accounted for in several ways, such as too much fire heat, unsuitable aspect, and escape of sulphur from the stokehole, each fatal to the growth of mushrooms. The aim should always be to imitate Nature as much as possible, and to produce similar conditions to those which obtain in the autumn, when mushrooms can be picked in large quantities in the open fields. A mushroom-house should always be erected on the north of a wall; the path should be made down the centre and sunk two feet below the ground level, which must be effectually drained. Two beds on either side should be made, the first being arranged on the ground, and built up to a depth of two feet six inches, with bricks set in cement. Three feet should be allowed between this and the top one. Piers must be run up at suitable distances, and arches turned to carry the upper bed, or, better still, use angle iron built in back and front, with stone slabs placed across, running up four-and-a-half inch brickwork to the same height as the lower bed. The roof must be either ceiled or thatched, the former being preferable if the roof is slate or tiles, but a well-thatched roof will answer the purpose. Very little fire heat is necessary at any season of the year, and much more harm is often done by the use of too much than of too little. It is a good plan to run a four-inch flow and return pipe along the path for providing heat in extremely cold weather. The maximum temperature of a mushroom house should be 65 degrees, but that most suitable for the growth of mushrooms is 55 to 60 degrees. The beds may be made at any time of the year, and the warm, moist atmosphere produced by them will prove of great assistance to quick growth. When beds are firmly and well made they should continue to bear freely for two months, but as soon as they show signs of being spent, and the mushrooms are poor in quality, remove them and replenish. The walls, paths, and beds must be damped down once a day, early morning being the best time, but twice in hot dry weather will be beneficial. Once a week damp down the paths with liquid farmyard manure.

For Exhibition.

Valuable prizes are frequently offered by some of our leading nurserymen, and sometimes by the various societies, for dishes of mushrooms, and, generally speaking, the classes are well filled, and form by no means the least interesting part of the exhibition. In a collection of vegetables of not less than twelve kinds in the month of November they will form a weighty dish with the judges, while in an ornamental collection of vegetables they are indispensable. The chief points to be considered are evenness and freshness throughout, and, if possible, they should not be cut till the morning of the exhibition. Place in shallow boxes in single layers for carriage, and finally arrange on dishes on a thin layer of bright green moss. The stems should have a piece cut off when staging, so as to give a fresh appearance, leaving about an inch of stem placed upwards. Good mushrooms should be of medium size, not quite fully developed, and the under gills ought to be flesh-pink, the stem solid and free from maggots, and the whole mushroom of good substance. Good spawn can be procured from very many sources; personally, I have chiefly depended on Cutbush's Miltrack for the past thirteen years. This is a very popular spawn, and has not once failed me.

Aldenham House Gardens. E. BECKETT.

"Lest We Forget."—This now celebrated phrase has other wide application than political. It is well to ask all who garden—amateur, cottager, or professional—not to forget that so far as the present most delightful winter is concerned, all is not as it may be, and the warmth of January or February does not constitute a genuine spring. The gardener who is tempted to hastily sow or plant now of things that in ordinary seasons would not be sown or planted for a month or so, will do well to remember that these very tempting mild winters are almost invariably followed by late cold springs; and when April and May are marked by numerous white frosts or visited by intensely cold cutting winds, then the condition of the unduly early sown or planted compare[illegible] with that of the crops got in at the ordinary time of the year. The [illegible] always is to act upon common practice and experience: to treat the winter, [illegible] mild or hard, as winter, and the spring as the sowing and planting season, and the result of your labours assuredly will be far more satisfactory.—A. D.

Plain Points about Peaches.—In the peach (with which may be [illegible] the nectarine) we have a fruit so delicious that it is small wonder that many [illegible] endeavour to grow it. Some succeed, some fail. Faults of pruning bring [illegible] to grief. They allow the trees to become smothered with old wood, and the [illegible] growths have no chance. When it is stated that it is on the latter that the fruit is borne, the magnitude of the error will be appreciated. Not long ago I observed a number of trees which were a mass of growths, the shoots crossing and [illegible] lacing, and many sticking straight out from the wall. These never matured [illegible] fruit, and, if the same system is pursued, they never will. There are many [illegible] in connection with peaches which have to be observed by those who are successful, but they are not very abstruse. Even the pruning, over which, as hinted above, so many stumble, is not complicated, and when once the main principle is grasped, only patience and judgment are wanted to achieve success. There are [illegible] matters of importance, the suppression of insects being one of them, but [illegible] all others only call for observation and perseverance.—W.

Water in the Rock Garden.

(*See Page Illustration.*)

Few things are more desirable in a garden than water, and fortunate indeed are they who have grounds traversed by a natural streamlet, however modest its extent may be. Whether in the shape of a fountain, a waterfall, spring, pond, lake or streamlet, water—unless it be a stagnant pool—adds light, life, and beauty to every garden, provided it is used to the best advantage and with due regard to effect. Unfortunately, the natural presence of running water in a garden is comparatively rare, and in most cases water, if desired, has to be introduced by artificial means, either through water-pipes, by land drains, or sometimes by open rills or gutters connected with a distant supply. But no matter by what means the supply may be obtained, the water visible in our gardens can give the best effects only when it appears to be perfectly natural. I am, of course, not speaking of fountains or fountain basins, but all irregular forms of water can be pleasing to the eye only when they appear to be entirely the work of Nature, and when any artificial means employed in their construction are entirely hidden from view.

Nowhere, perhaps, is the masking of what is artificial of greater importance than in the case of water in a rock garden. Rocks, even when arranged with the utmost care so as to represent Nature's work, would at once lose their natural effect if the water seen among them reveals its artificial origin by visible traces of cement work. A case in point is given in the accompanying full-page illustration, produced from a photograph in a rock garden constructed by myself on behalf of Messrs. Veitch and Son, Exeter, for one of their clients in the county of Devon. The picture shows only a small corner of the pond among the rocks, but this is sufficient to illustrate the principle of masking artificial groundwork. Although the whole of the pond had to be formed of cement-concrete, not a particle of that work can be seen anywhere, and in the picture the water margin on the right-hand side appears as grass sward dipping naturally below the surface of the water, while on the left it consists of rocks, also continued below the water level. My method of producing this effect consists in having the unavoidable cement work so arranged as to form a sort of step or shoulder about eight inches wide all around the pond, and not less than six or eight inches below the intended water level. This furnishes an excellent rest for the stones, the turf, or what ever other material may be used to form the margin. Another great advantage of this method is that a portion of the soil covered by turf or enclosed by rocks must obviously be water-soaked without holding stagnant water, and among the ornamental plants of all sizes which love the waterside there may be found an endless number which delight in just such a position. The large plant seen growing so luxuriantly on the left side is a specimen (over six feet high) of Spiræa gigantea (Spiræa Kamschatica), and its luxuriance, like that of many other plants around the margin of this pond, is undoubtedly due to the fact that the roots of the plants have free access to the water. In the pond itself numerous choice water lilies are flourishing, of which one, a specimen of Nymphæa marliacea albida, is well shown in the illustration.

The background of the picture shows a cave which answers the purpose of a cool and shady summerhouse, and the fissures of the rocks are filled with choice mountain plants from various parts of the globe. Shady recesses are given up to Ramondia pyrenaica, Linnæa borealis, primulas in variety, &c. Above the cave are seen Lotus peliorhynchus, Arctostaphylus Uva-ursæ, Tropæolum tuberosum, and many more, while special positions have been allotted to the smaller mountain gems, which here are enabled to grow as they please without the danger of being overrun by plants of coarser growth. As it is, however, not to the rock garden generally, but to the water garden, that I wish to devote this article, I will briefly state the result of my experience with water gardens, first on a small scale and in connection with rocks, and then with ponds and lakes on a larger scale, and the plants most suitable for their adornment.

Fountains, Springs, and Brooks.

No form of water in a rock garden can possibly be worse than a fountain. Among the geometrical surroundings of a formal flower garden or in front of a regular terrace a fountain may be made an attractive feature, but in connection with rocks it is altogether out of place, because there it is not in harmony with its surroundings. A well-arranged rock garden should resemble Nature's work, and a water-squirt of any kind among what should be wild and picturesque scenery would be absurd.

A spring among the rocks is perhaps the simplest form of water, and its very simplicity appeals to us. If the spring be a natural one it will probably need very little to be made most attractive; the ground around it would be saturated with moisture, and would furnish an unrivalled home for all kinds of beautiful plants. But if the spring should be an artificial one its origin must be concealed. A capital way of effecting this is to place the rock stones in such a position as to form a deep cleft or small cave, so arranged that its end cannot be seen, for the uninitiated will not fail to imagine a great depth of fissure where they cannot see the end. If the water, before emerging from this miniature cave, is allowed to fall into a small pool not less than one or two feet deep we get that delightful murmering sound so pleasing to the ear and so soothing to the mind. If in addition to this the plants chosen to embellish the immediate surroundings are such as would impart to the scene a character of natural grace and beauty, our spring among the rocks will furnish a charming picture, full of life, and one that cannot fail to please even the most fastidious.

The brook or streamlet is another form of water most suitable for the rock garden. A brook, whether rapidly leaping from rock to rock or slowly meandering among boulders and recesses, is at all times most refreshing, both to the plants that mark its course and to the eye that beholds them. Natural streamlets in our rock gardens are things often desired but seldom met with. In most cases, therefore, art has to supply the deficiency. The size of such a stream in the rock garden must of course depend on the volume of water at command, but no matter what may be the extent of the supply, we must shape our artificial brook in such a way that no one would suspect its artificial origin. Only by observing Nature can we acquire the ability to impart a natural appearance to our own handiwork, and according to the laws of Nature we must therefore proceed. One of the most apparent of those laws is the approximate parallelism of shore lines in streamlets. When flowing water meets with a rock, or any other obstruction which might divert its course, the immediate result is that opposite such an obstacle the shore or bank is encroached upon, and if it be of a soft or yielding nature, a comparatively large hollow in the bank will be washed out. In other words a shore line which is convex on one side will be concave on the other. When streamlets are formed artificially and on a small scale, this law has to be well observed. In nine cases out of ten cement concrete will be the only practicable means for forming the sides and bottom, as such work is practically everlasting, and can easily be made to appear natural work. Even when good impervious clay might be used to prevent waste of water, it is nevertheless easily washed away by a moderately strong current, and moreover, the water would not be clear, while the banks would be subject to the attacks of water rats, and would soon crumble away. On the other hand, cement work can easily be covered, at the bottom by round stones and river gravel thrown in while the cement is wet, and at the sides by rocks and turf arranged in a similar manner to that already described. This method will allow irises, Astilba rivularis, and other moisture-loving plants, to send their roots into the water as is their wont in the case of a natural streamlet.

Waterfalls.

Waterfalls are, perhaps, of all forms of water, the most effective, and the nearest approach to that wild character which is at once so charming and yet so imposing among natural rocks. But in the sense of a water-garden, such falls do not afford the same facilities for floral embellishment as the sides of ponds or streamlets. I will, therefore, abstain from giving elaborate details regarding the construction of waterfalls. Suffice it to call attention to the general rule that waterfalls in unbroken sheets are more or less monotonous, and that it is chiefly in a broken fall that picturesque effects attain their greatest perfection. When water can be had in abundance and waste does not matter, boulders of rock irregularly distributed are the best means of producing that effect. But when water is scarce and supplied artificially by a small waterpipe every drop of water becomes of value, and it behoves us to use it to the best possible advantage and with due regard to economy. One of the best means of showing the water at its best in this case is to let it descend in front of a cave when, in consequence of the dark background, every drop of water will reflect the light and form such a contrast against the dark background as to be clearly visible even if only a modest dripping fall is attempted. It goes without saying that in every waterfall the actual source of the water should be carefully concealed.

Ponds in the Rock Garden.

Ponds will, as a rule, be of limited extent, and unless a naturally copious supply of water can be had it will nearly always be best to use cement concrete, and mask the same in the manner already described. With regard to the shape of a pond, it has to be borne in mind that a pond in most cases is a form of widened streamlet, and Nature's hints with regard to the banks of the latter must, therefore, in a broader sense apply also to the pond. A depth of two to two and a half feet is enough to grow some of the choicest aquatics, and will, as a rule, be sufficient for most ponds in connexion with a rock garden. When planning a pond, care should be taken to introduce it into the naturally lowest part of the ground. For the concrete a thickness of six inches, consisting of five parts of broken stones to one part of Portland cement, should be sufficient if the surface is afterwards smoothed with a thin layer of cement and sand in equal proportions. A pond receding into a cave is very picturesque, especially where in shady recesses ferns and other plants abound; but in every case the cement work must be finished before the work of arranging the rocks is begun.

Bogs.

Boggy beds can often be formed by the overflow from a pond. Where it is not advisable to let such overflow filter away gradually in well-drained peaty soil I often construct an underground watertight basin, which can be filled with water or emptied at will by the simple turning of a tap. Layers of broken stone, peat, leafmould, sand, &c., are filled up to the required height, and can thus be kept saturated with water or drained dry according to the requirements of the plants employed.

Exeter. F. W. Meyer.

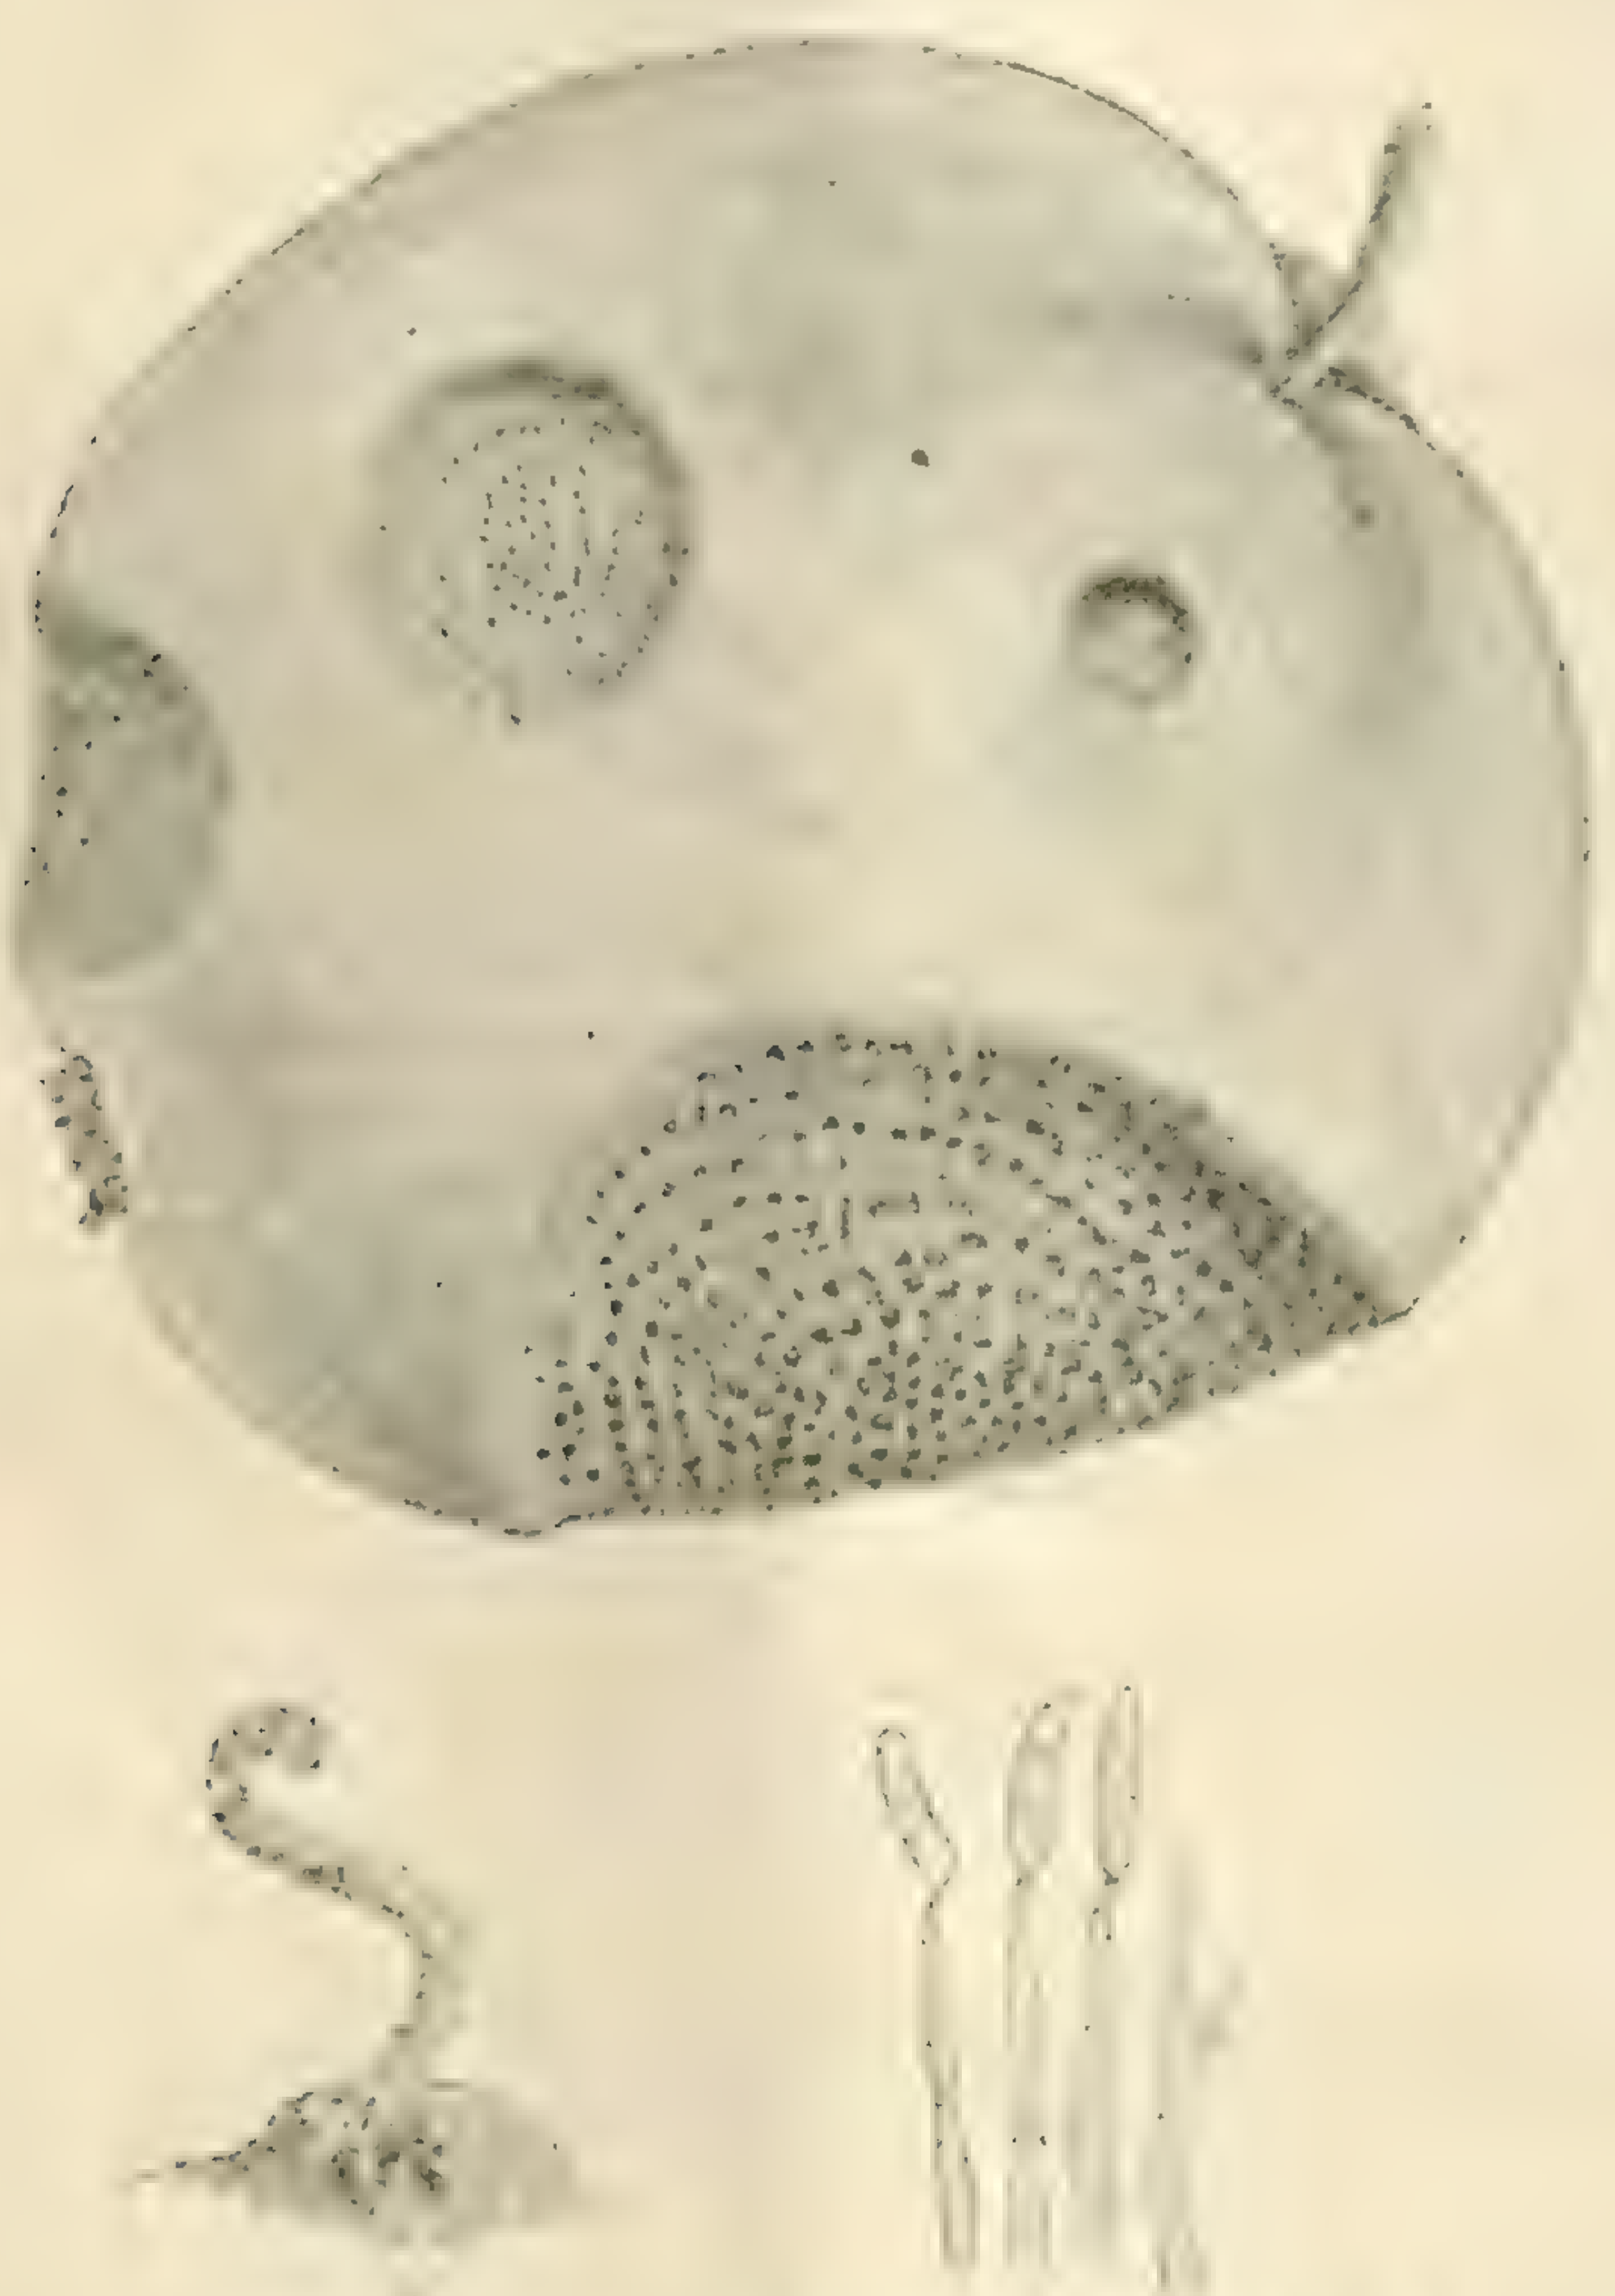
Marguerites.—These beautiful plants seem to grow rather than diminish in popularity. The quantities now grown for market are enormous, and this in spite of the fact that home cultivators have taken up the plant widely. Their free flowering, graceful character, and easy culture are largely responsible for their great popularity. Healthy bushes well furnished with flowers are delightful objects, and they look equally well in conservatories, windows, boxes, and on balconies. Like geraniums, they may be propagated at almost any season of the year, sturdy young side shoots three or four inches long, severed just below a joint and inserted very firmly, being suitable. If it is particularly wanted to bring them along quickly they may be placed in a propagating case or otherwise be afforded the benefit of bottom-heat, but this is not at all necessary for insuring rooting. They will do that in a greenhouse, if possible with a hand-light or bell-glass over to keep them close, or in a frame. If stopped so as to cause them to branch freely and potted firmly in a fresh, fertile, porous mixture they will soon develop into handsome flowering plants.—W.

BITTER-ROT IN APPLES.

THIS general and very destructive disease is caused by a minute fungus called Glœosporium fructigenum, Berk. Although the disease is most conspicuous on the ripe fruit, nevertheless the apples are usually first attacked by the fungus when about half grown. The earliest external indication of the disease consists in the presence of one or more discoloured spots; these gradually increase in size, still retaining a more or less circular outline. Not unfrequently two or more of these spots increase in size until they run into each other, and thus form large, irregular disease patches, which continue in most instances to extend until the entire surface of the apple is covered. As the disease progresses the patches become dark brown in colour and sink a little below the level of the healthy portion of the surface. This sinking of the surface is caused by the mycelium or vegetative portion of the fungus breaking up the tissue of the apple, which serves as food for the fungus. The brown, disease portion of the apple has a very bitter, disagreeable taste, hence the popular name of the disease.

Development of the Fungus.

After the brown spots have been present for some time, their surface will be seen to be covered with minute black points, which are often arranged in irregular concentric circles. These points, when examined under the microscope, are seen to consist of numerous upright branches of mycelium, compacted into a bundle, and further examination shows that each upright branch bears a minute reproductive body or conidium at its tip. The conidia are produced in immense numbers, and ooze to the surface of the disease spots under the form of very fine hairs or tendrils, being stuck together by a viscid substance. On reaching the surface of the apple, the strings of conidia are dissolved by dew or rain, each conidium being capable of inoculating a young, healthy apple, and thus starting a new centre of disease. Bearing in mind the rapid and continuous production of such immense numbers of conidia or reproductive bodies of the fungus, it can be readily understood by what means the disease spreads so rapidly when it has once gained a foothold in an orchard, the conidia being washed from diseased on to healthy fruit by rain, or carried by insects, birds, wind, &c., and if the surface of the fruit is damp, the conidia germinate, and enter the tissue of the apple within a few hours, and, under favourable conditions, within a week a disease patch bearing mature conidia is the result. Damp, dull weather favours the spread of the disease, whereas its extension is checked by the opposite conditions of dryness and light; hence, crowding of the trees should be avoided, and, furthermore, pruning should secure a good circulation of air, and prevent the retention of too much moisture in the individual trees.



APPLE INFECTED WITH GLŒOSPORIUM FRUCTIGENUM.

Having indicated the method by which the fungus spreads during the summer season, it remains to be demonstrated by what means it survives throughout the winter, and puts in an appearance again just in time to infect the young fruit. It is certain the fruit is the only part attacked, and that there is no perennial mycelium present in any part of the apple tree to furnish the conidia that inoculate the young fruit; hence the germs must be furnished from some other source than that of the tree itself. Diseased apples, especially when of considerable size before they are attacked, soon fall to the ground, and if allowed to remain the fungus continues to furnish successive crops of conidia, many of which find their way to the surface of healthy fruit, which in turn becomes diseased. But more than this, the mycelium of the fungus permeates every part of the fallen apple, and the latter does not rot and disappear, but becomes converted into a dry, leathery, shrivelled ball, and in this condition the mycellium passes the winter in a resting condition, becoming active again the following spring. If one of these fallen mummified apples is examined in May or June its surface will be seen to be covered with little black points; these correspond to the mature conidia of the glœosporium, which are produced by the mycelium of the fungus after a winter's rest in the dried-up tissues of the decayed apple, and produced just at the season when the young apples are ready for inoculation, when the activity of the fungus commences in earnest. When the fruit is attacked quite young it usually remains firmly attached to the tree in the mummified state, and produces conidia the following year, as already explained in the case of the fallen apples. In storing fruit great care should be taken to pick out all apples showing the least indication of the disease, otherwise healthy fruit will become diseased, especially if allowed to remain for any length of time in a heaped-up condition. An American observer has stated that the disease also attacks pears, peaches, grapes, &c., in the United States.

Methods for Preventing the Disease.

From what has already been stated respecting the mode of life of the fungus, it is seen that the appearance of the disease depends on the presence of decayed fruit which has remained over the year, either lying on the ground or hanging on the trees. All diseased fruit should be gathered and burned; do not throw it on the manure heap nor into the pig-sty; nothing in reality is gained by so doing, and a great risk is run, and do not, above all, out of "pure cussedness," try some other method not recommended, hoping it may answer as well, or better, than the method of prevention specially asked for, and then ignored. Where the disease has previously existed it is imperative that the trees should be thoroughly sprayed with a solution of potassium sulphide—half an ounce to a gallon of water—the first spraying just after the fruit is set, and again after an interval of three weeks. The spraying should be again repeated if the disease appears, as by this means it is held in check. As the fungus is very abundant and widely diffused, a spraying after the fruit is set would always be a wise precaution against the possibility of infection from your neighbour's orchard, who does not believe that "prevention is better than cure," and consequently never sprays, but accepts what he considers as the inevitable.

Store-rooms that have contained diseased fruit should be sterilised before they are used again. Spray the floor with a hot solution of potassium sulphide, one ounce to a gallon of water; the walls, and, in fact, every part of the interior of the building, should be treated in a similar manner, not forgetting the furniture, especially the trays and shelves, where spores are most likely to lie nascent until their opportunity arrives. If these precautions were persistently carried out the amount of bitter-rot and other ripe fruit diseases would be reduced to a minimum, instead of which one enters an elaborate storehouse with feelings of awe, arising from the preliminary talk about equal temperature, perfect ventilation, &c., and is surprised to find a hamper of rotten fruit under a shelf, and a mummified apple reposing in a corner, as if placed there by its owner as a warning to apples not yet mummified, and emerges from the spore-laden atmosphere feeling, but not daring to say, that, whether through gross ignorance or gross neglect, all concerned are equally culpable.

DESCRIPTION OF THE FIGURES.—1, Apple, showing bitter-rot disease, natural size; 2, a string or tendril of conidia oozing out of a diseased spot, mag. 80 times; 3, Branches of mycelium, each bearing a conidium at its tip, mag. 400 times.

G. MASSEE.

RIPENING OF LATE PEARS.

FREQUENT reference has of late been made in the pages of the GARDENERS' MAGAZINE to the premature ripening of late pears this season, and so far as I have noticed, it is the southern growers that have drawn attention to it; and by them, the dry, warm summer and mild autumn of last year appears to be held as the main cause of the evil. Here, in Scotland, the ripening of late fruit has been of much the same nature as described by others, and our most reliable varieties that are usually sound and of good quality until the end of February, were ripe at Christmas, and had to be used shortly after. Of these Beurre Sterckman's and Ne Plus Meuris, two varieties that seldom vary much in their season of ripening, were as bad as others; while Easter Beurre and Beurre Rance, which should be the latest of any, scarcely reached maturity before decay set in.

In our case neither much heat nor drought was sufficiently in evidence here last summer to have any great effect upon the keeping of the fruit; in fact, I had thought that the want of more sun and less moisture was the reason of the fruit keeping so badly, as with the exception of October and November, in which the rainfall was below the average, all the other months were considerably above. The total for the year being 45 inches, which was the highest registered since 1883. I may state that the pear crop of last season was very unsatisfactory throughout the south of Scotland, as, coupled with a light crop, the fruit was small, even when grown against walls with the most favourable aspects for full development; and the mid-season varieties came to maturity in a more irregular manner than I ever before remember, and mostly in advance of their usual time of ripening. The only fruits at present that are keeping well and fit for dessert are those of Bergamotte D'Esperen, which were grown on cordon trees. These are of excellent quailty, but very small in size, a point that is not of so much importance now as it would be earlier in the season.

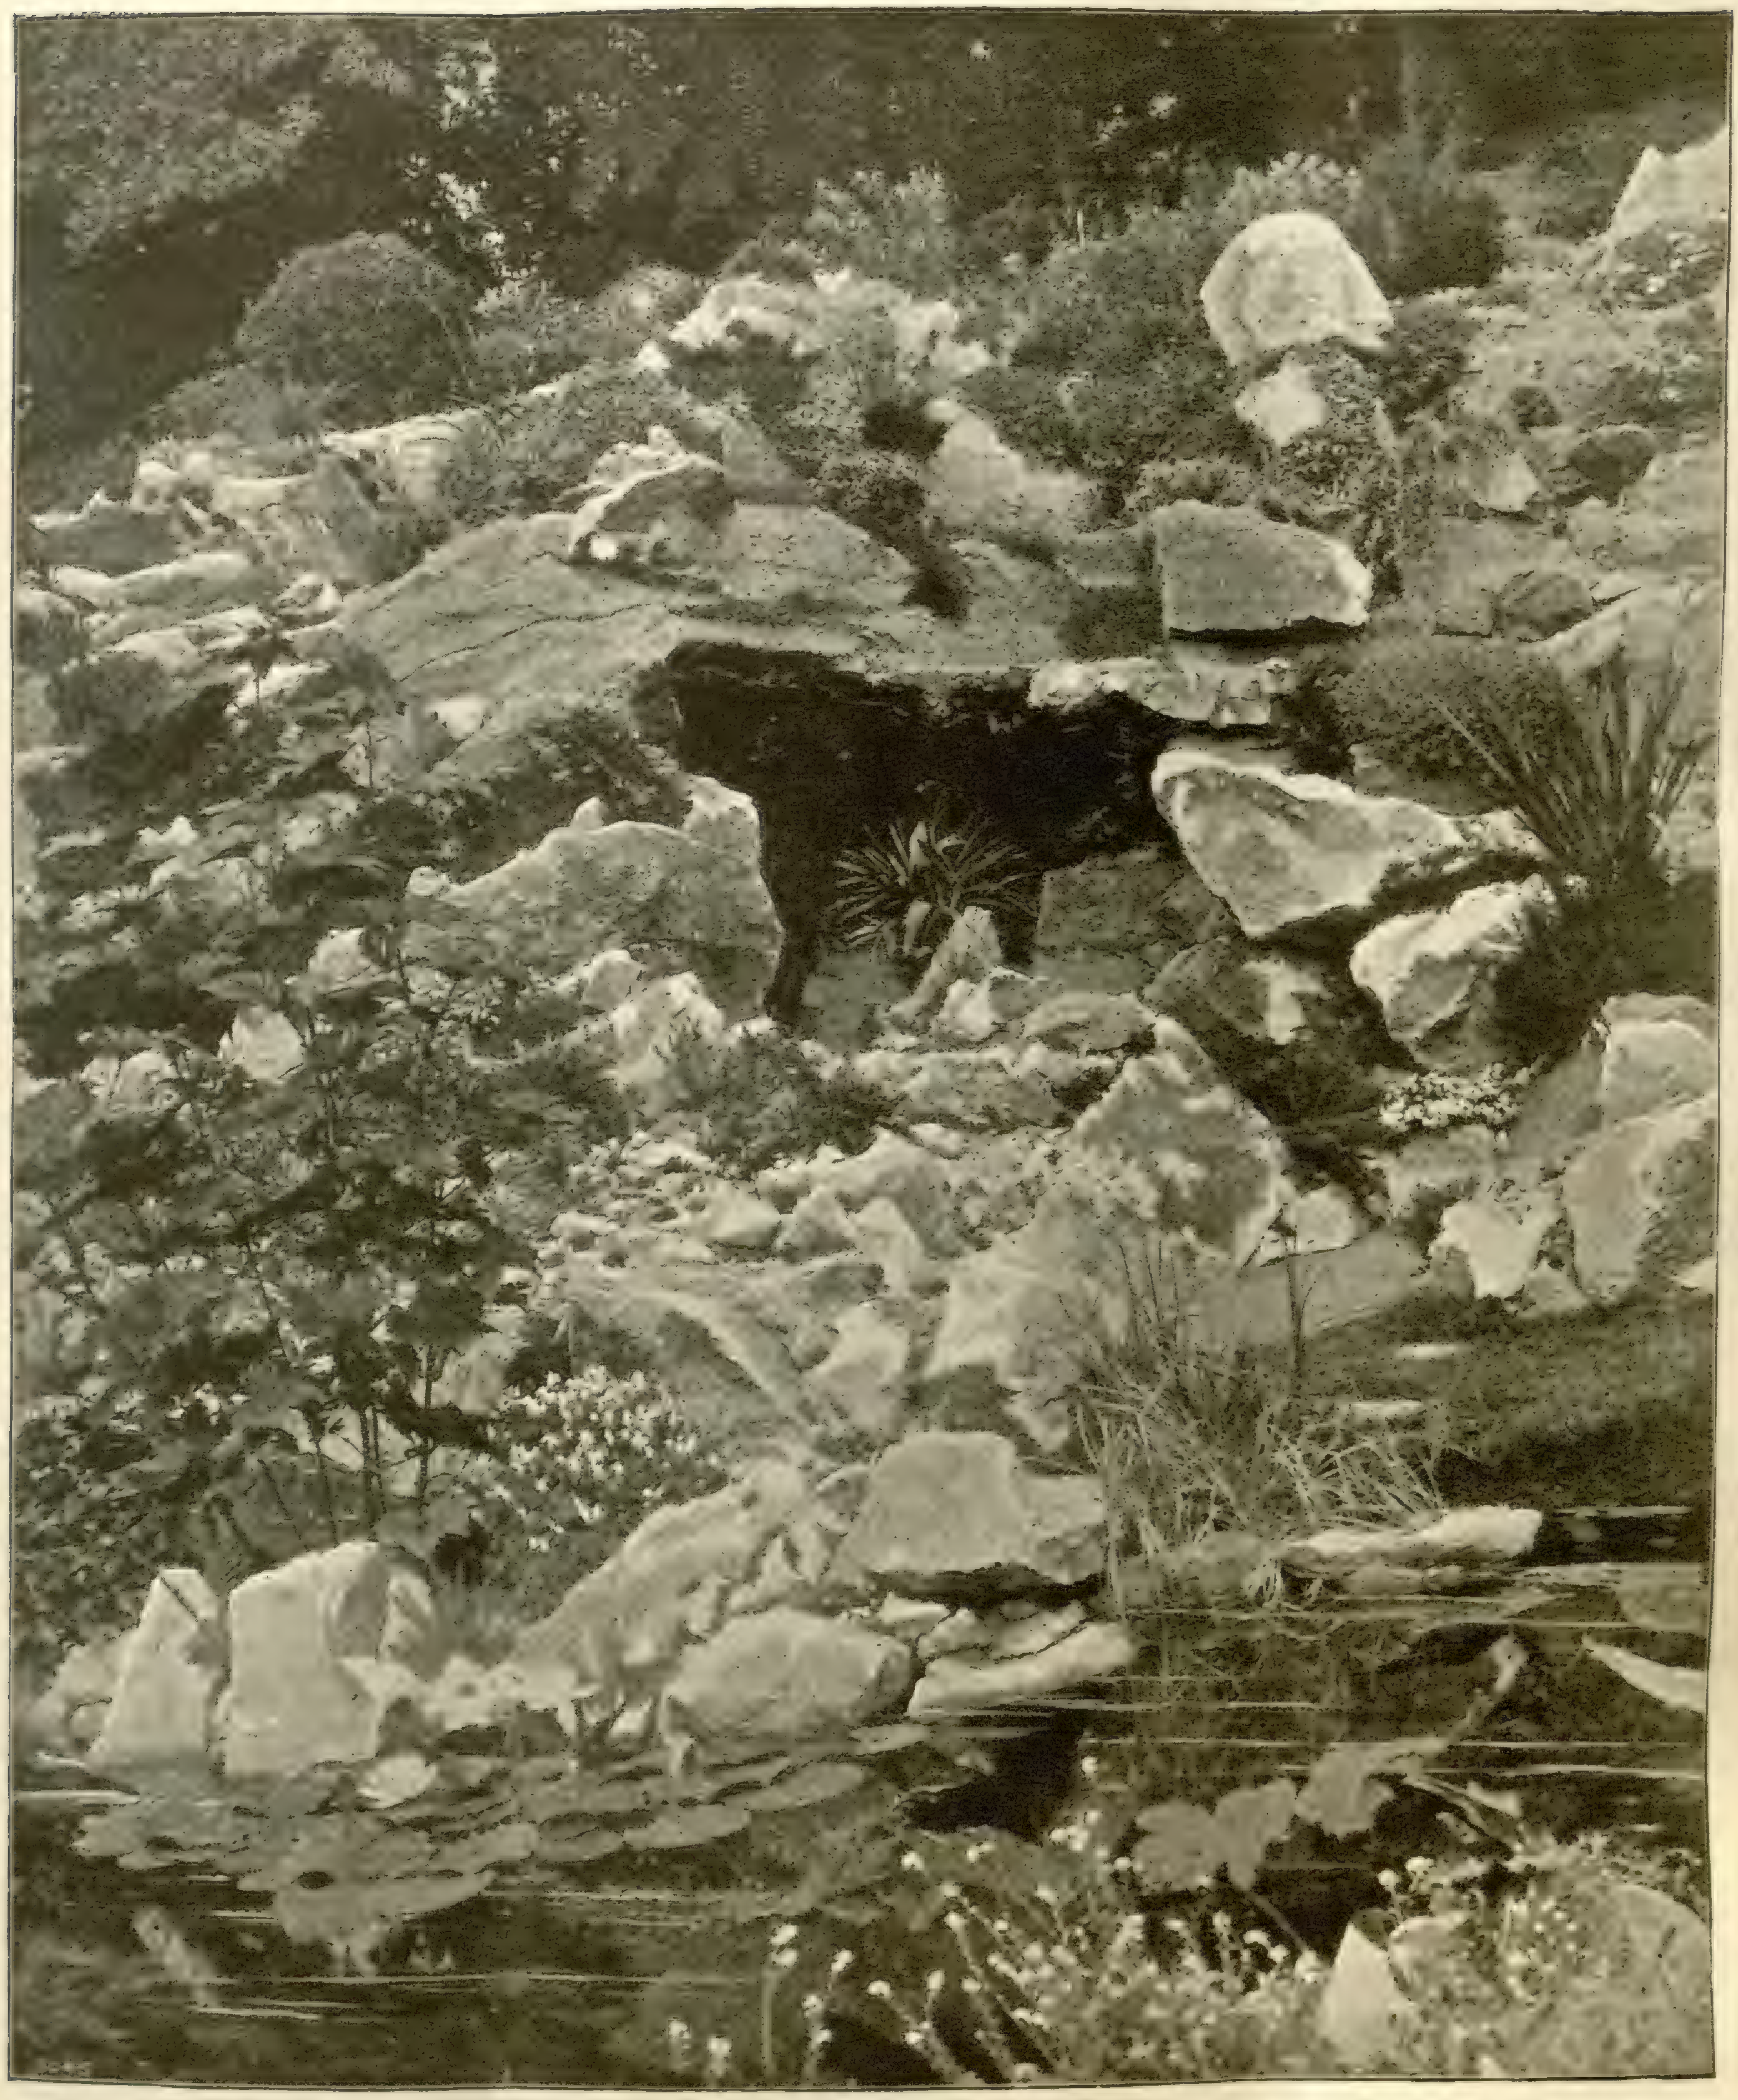
JAMES DAY.



WATER IN A DEVONSHIRE ROCK GARDEN. (*See page* 129)

NOTES ON ORCHIDS.

Paphiopedilum Chamberlainianum.

This Sumatran orchid that has been well known for the last five or six years is figured in the current issue of the *Bot. Mag.*, t 7,578. It is especially noticeable by reason of its perennial raceme, which slowly elongates and produces flowers, a pair often being open at the same period. The rounded dorsal sepal is bright green, with a red-purple base and nerves; it has waved and ciliate margins. The petals are bright green, narrow, linear, margined with purple, and with purple streaks on the green ground; they are twisted at about half their length, the twist commencing from above in one and from below in the other. The prominent lip is rich rose-coloured, and specked with red. Messrs. Sander and Co., of St. Albans, introduced the species, and it was named by Mr. James O'Brien in honour of the Right Hon. J. Chamberlain, Secretary for the Colonies. The species requires a stove temperature.

Angræcum sesquipedale.

This popular orchid is not always managed with conspicuous success, but Mr. G. Emery, gardener to T. H. Nash, Esq., Garland Hill, St. Paul's Cray, Kent, seems to understand it perfectly. A photograph sent, though not suitable for reproduction, represents a fine specimen carrying two spikes, one bearing four and the other five of the large creamy-white long tailed flowers that invariably attract attention. The winter-flowering form of this most celebrated of the orchids from Madagascar is not very popular in town collections, as the flower buds are so often damaged by fog. Outside the smoke radius, however, it develops its flowers to perfection.

Epidendrum Medusæ.

The accompanying illustration represents a fine specimen of the above orchid — more generally known under the generic name of nanodes—grown at Oswald House, Edinburgh, the proprietor of which, J. Buchanan, Esq., is an ardent lover of this order of plants. Although the specimen figured is well shown as regards compactness and density of foliage, yet it does not do justice to the size. There are three baskets, and the two largest are two feet square, and if a measurement of the foliage was taken they must be quite two feet six inches or more across; indeed, they are said to be hardly equalled in the kingdom. Mr Wood, the energetic and capable gardener here, has propagated this singular plant by division, and the second basket made up bids fair to rival or outstrip the original in point of size. Regarding the culture bestowed on these plants, the position they occupy is one near a side ventilator in a small span-roofed greenhouse, where flowering plants, such as primulas, hyacinths, cinerarias, &c., are grown and flowered at this season; and they are at all times given good supplies of water overhead, while the ventilator is almost constantly open, except during frosty weather. Here the specimens have always been found upon my frequent visits during the past few years, and when in flower they are always objects of interest and good cultivation. This native of Ecuador was introduced by Mr. Backhouse, of York.—R. L. Harrow, *Edinburgh.*

Specimen of Epidendrum Medusæ, grown at Oswald House, Edinburgh.

Cattleya aurea.

This species is not so variable as C. Trianæ, C. Mossiæ, or C. labiata, but there are a few notable and distinct forms fairly well known. Messrs. Linden and Co. seem however, to have obtained an importation showing considerable variation, judging from the double-page illustration in the *Lindenia* t. 598, 599. Five forms are figured and described, all of them having flowered at the Moortebeek establishment. *Cattleya aurea splendens* has a very fine lip with a handsomely waved margin; it has a rich crimson purple apex and stripes of the same colour over a groundwork of deepest yellow at the base; the margin is edged with rose; petals are paler yellow than the sepals. *C. a. magnifica* has an attractive labellum, the apex being crimson purple tapering into a broad central belt of red purple stripes that passes down the centre between two very broad golden areas to meet the red veinings on the throat; the golden portions are edged with crimson purple; petals very broad. *C. a. Chotekiana* is very distinct, its broad sepals and petals being coloured deep yellow; the lip is very dark, the whole centre and apex being violet-purple shaded with crimson, this colour radiating vein-like into the surrounding dark yellow. *C. a. musaica* seems well named, for the lip is peculiarly marked; it is margined laterally with rose dotted with purple; the apical margin is pale yellow, and sets off the rosy purple apex; the larger portion of the lip is yellow spotted freely with orange and red. *C. a. aurantiaca* derives its name from the large deep orange-coloured areas that flank the central purple and red band of the lip; the apex is crimson purple, and the margin of the same colour.

THE PROCESS OF DENITRIFICATION.

The subject of denitrification has, Professor R. Warrington, F.R.S., states in the current issue of the *Journal* of the Royal Agricultural Society, been [illegible] investigated by many scientists during the past thirty years, with the [illegible] that a great deal of the work done has been already forgotten, and is [illegible] in the ignorance of a fresh generation of workers. This scarcely [illegible] occurrence happens most frequently when, as in the present case, the [illegible] worker belongs to a different nationality from that which produced [illegible] investigators. An historical treatment of the subject would perhaps be unsuitable. Prefacing, therefore, his remarks by saying that Dr. Angus Smith, of Manchester, in 1867, was apparently the first to observe the destruction of nitrates with the evolution of gas in decomposing organic solutions, he proceeds to take a general view of the facts connected with denitrification.

The reduction of nitrates which occurs in solutions, or soil, containing readily oxidisable organic matter is of several distinct kinds. The reduction [illegible] simply from nitrate to nitrite; or it may be from nitrate to nitric oxide gas; or to nitrous oxide gas; or, finally, to nitrogen gas. The first form of reduction does not necessarily involve any loss of nitrogen; all the others do involve a [illegible] nitrogen, as the product escapes in the form of gas.

The reduction of nitrates is occasioned by various species of bacteria. [illegible] action in question only occurs in the presence of these living organisms [illegible] established by Meusel (1875) in the case of natural waters, and afterwards [illegible] by Dehérain and Maquenne (1882) to hold true in the case of soils. If all living organisms are destroyed in sewage or soil—if, to use modern language, these mediums are sterilised—neither nitrification nor denitrification will occur.

Bacteria reduce nitrates by bringing about the combustion of organic [illegible] the oxygen of the nitrate, the temperature distinctly rising during the [illegible] When circumstances are favourable to the process of reduction, the [illegible] nitrate reduced is determined by the quantity of combustible organic [illegible] present. The combustion of the organic matter, and reduction of the nitrate, [illegible] take place in the absence of air, in the same way as gunpowder—composed of nitrate, charcoal, and sulphur—is capable of burning under water. In the presence of air, the oxygen which it contains takes the place, more or less, of the oxygen of the nitrate, and the reduction of nitrate is either diminished, or the oxidation of the organic matter much increased. The whole action is quite [illegible] to the familiar combustion of food in the animal body; or to the combustion of organic matter which occurs in plants, and notably in those which, as is the [illegible] with fungi, are destitute of chlorophyll.

Different species of bacteria behave very differently in a mixture of a [illegible] and organic matter. Many species of bacteria are incapable of reducing a [illegible] though quite capable of effecting the combustion of organic matter [illegible] oxygen. The reduction of a nitrate to a nitrite, but not to the state of [illegible] however, a very common property of bacteria. Gayon and Dupetit (1866) were the first to isolate the species of bacteria reducing nitrates to gas; two organisms having this property were separated by them from sewage. Quite recently [illegible] and Stutzer (1895) have isolated denitrifying bacteria from horse dung, and [illegible] straw. These organisms differ in several ways. The one obtained from [illegible] capable of reducing nitrates to gas in the absence of oxygen, and in the [illegible] much oxygen its action is hindered, and finally ceases. The bacterium [illegible] dung develops exclusively in the presence of oxygen, but it can reduce [illegible] only when associated with another organism of anaerobic character; that is, [illegible] developing in the absence of oxygen. When the two organisms are [illegible] reduction takes place in the complete absence of oxygen, but the action [illegible] active as soon as a little oxygen is present, and, when plenty of organic [illegible] present, the process is apparently not hindered by a full supply of that gas. [illegible] is no evidence that either straw or horse dung contains only, or always, [illegible] denitrifying organisms just described.

Soil contains an abundance of reducing organisms, including those [illegible] nitrogen gas. When broth containing one per cent. of nitre is infected [illegible] particle of surface soil, and kept in a warm place, a quantity of gas [illegible] taining nitrogen is produced, and the nitrate will entirely disappear. Soil [illegible] with a one per cent. solution of sugar, containing nitre, rapidly [illegible] latter; the gas produced contains nitrous oxide and nitrogen. Any [illegible] organic matter readily oxidised by bacteria may be used to bring [illegible] reduction of nitrates. In the trials made by various experimenters, [illegible] asparagine, starch, sugar, humus, fats, tartrates, citrates, acetates, and [illegible] have all proved effective for this purpose. The presence of some [illegible] plant food, and of phosphates, potash, and the other ash constituents of [illegible] of course necessary for the growth and activity of the reducing bacteria.

It is clear from what has gone before that denitrification may be [illegible] occur whenever a suitable mixture of nitrate and organic matter is infected [illegible] dust under the conditions favourable to the action. The early [illegible] Angus Smith in England, and of Th. Schloesing in France (1868), [illegible] organic solutions, as sewage, diluted blood, tobacco juice, and sugar [illegible] when undergoing fermentation or putrefaction, actively reduced nitrates, nitrous oxide and nitrogen being evolved. Whence did these mixtures obtain the bacteria necessary for this action to take place? Nothing had been [illegible] duce the organism; indeed, at the date of these observations it was [illegible] that the action was brought about by bacteria. The answer is plain: [illegible] solutions obtained the organism which reduced nitrates by ordinary [illegible] atmospheric air.

Having grasped the facts now before us, we are disposed to smile [illegible] gravely informed that straw bears on its surface the organism reducing [illegible] nitrogen gas, and that it is in consequence of this fact dangerous to use it as a manure for soils. It is doubtless quite true, as we are informed by Wagner and others, that rye-straw, placed in water containing saltpetre, slowly reduces the nitrate present. But this result is not due to any peculiar property of straw; the action which occurred would equally have been observed if other [illegible] matter contaminated with atmospheric dust had been made use of. [illegible] experimenting in this way, has obtained similar results when using [illegible] the straw of wheat, maize, or haricot bean; lucerne silage ([illegible] or maize cake. That atmospheric contamination was the source of [illegible] reducing nitrates which were present in these experiments is strikingly [illegible] the case of the maize cake.

It is assumed by the German experimenters that the solid [illegible] herbivorous animals, and especially that of the horse, is peculiarly [illegible] organisms reducing the nitrogen of a nitrate to gas; the only [illegible] supposition is, apparently, the marked power of reducing nitrates [illegible] these excrements. Wagner tells us that if a hundred grams of [illegible] added to a thousand grams of water containing five grams of saltpetre, [illegible] whole allowed to stand in a warm place, the nitrate will disappear in a few days, the escape of gas being shown by a brisk effervescence of the liquid. [illegible] hasty conclusions have been arrived at during the discussion of the [illegible] before us that we must just point out that in the case of an action like denitrification, requiring the concurrence of several conditions, each of them equally essential, the activity of this action in any particular case cannot be taken as proof of a special preponderance of one of these conditions, but rather as showing that all are fully present.

There is, however, one reason which would lead us to expect that animal excrement would contain a relative abundance of the dentrifying organism. If we may assume, as we probably may, that the denitrifying bacteria present in the food pass uninjured through the intestines, it is evident that they will occur in larger proportion in the solid excrement than in the original food. If, for instance, a horse is fed on hay, and digests one-half of the food consumed, the dung will then contain twice the proportion of the denitrifying bacteria originally present in the food. The proportion of the organisms supplied by different kinds of food must vary greatly. If the bacteria are, as we assume, deposited from the atmosphere, and lie in all cases on the surface of the food, their proportion must depend largely on the extent and character of the surface, and on the length of exposure to the atmosphere. A hundred pounds of hay should contain a far greater proportion of bacteria than a hundred pounds of green mangel or turnips. From this point of view there is thus some ground for assuming that horse excrement will be richer in denitrifying organisms than cattle excrement.

Before further discussing the question before us we must, observes Professor Warrington, turn once more to the results of former investigations, and see what are the precise conditions necessary to induce denitrification.

Schloesing (1873), in his investigation on the rate of nitrification in soil, kept various portions of the same moist, humous soil, in atmospheres in which different proportions of oxygen were constantly maintained throughout the experiment. He found that the quantity of nitrate produced in the soil steadily diminished as the proportion of oxygen in the air decreased; when, however, no oxygen was present, denitrification took place, and the nitrates originally contained in the soil entirely disappeared. He repeated the experiment, this time adding a known amount of saltpetre to the soil. He found that such a soil, placed in a vessel containing very little air, first absorbed all the oxygen present, and then evolved a considerable quantity of gas; this gas contained nitrogen equivalent to the whole of that contained in the saltpetre added. The consumption of the oxygen of the air had thus determined denitrification.

The supply of atmospheric oxygen to a soil is effectually prevented if the soil is kept saturated with water; this condition alone is sufficient to set up an energetic denitrification. In an experiment made by Professor Warrington in the Rothamsted laboratory in 1880, and published in the R.A.S. journal in 1881 (p. 332), seven pounds of dry, finely-powdered loam were placed in a percolator, and thoroughly saturated with water; the column was about eight inches deep. The nitrates naturally present having been entirely removed by the passage of water through the soil, a known quantity of nitrate of sodium was placed on the surface. After a week had elapsed a small quantity of water was placed each day on the surface of the soil, and the drainage water removed and analysed. When nitrates no longer appeared in the drainage water it was found that only twenty-one per cent. of the nitrate applied to the soil had been recovered; seventy-nine per cent. had been lost. The mode in which this loss had occurred was evident to the eye; the column of soil, though always kept in a saturated condition, was cut across about the middle with large transverse fissures, the result of the formation of gas within the soil. In another experiment, made with the same soil under identical conditions, in which an equivalent quantity of chloride of sodium was employed, the whole of the salt applied was recovered in the drainage water, and no fissures appeared in the column of soil.

A recently-published experiment by Bréal furnishes a further excellent example of the active denitrification which takes place in a soil kept saturated with water. He placed some garden soil in a percolator and consolidated it by pressure; the column was about fifteen inches high. Water, more than sufficient for saturation, was then poured upon the soil. When the water had run through it was poured back again over the soil, and this treatment was continued for some time. The soil at the commencement of the experiment was in an active state of nitrification, and the drainage water was at first rich in nitrates, but at the end of three weeks the nitrate had entirely disappeared from the drainage water, though no water had been removed from the soil.

We have now the conditions which bring about a loss of nitrogen by denitrification plainly before us. There are needed: 1. The specific organism. 2. The presence of a nitrate and suitable organic matter. 3. Such a condition as to aëration that the supply of atmospheric oxygen shall not be in excess relatively to the supply of organic matter. 4. The usual essential conditions of bacterial growth, as plant food, and a suitable temperature.

Of these conditions, the supply of organic matter is by far the most important in determining the extent to which denitrification will take place. An abundance of the special organism is of comparatively little importance; for, if the conditions are made favourable for its growth and development, it will increase with such rapidity that the number of organisms originally present will soon become a matter of indifference. Nothing, however, will compensate for a deficiency of organic matter; if this is small in quantity, the action will be strictly limited in extent, however large may be the supply of the specific organism. This fundamental principle of the reaction has been strangely overlooked by the German investigators when interpreting the results of their experiments. They have sought to explain the denitrification in their experiments as due to the supply of additional organisms to the soil in the form of manure, when the results were really due to the supply of an excess of organic matter.

In Gayon and Dupetit's investigations the preponderating influence of the quantity of the organic matter present is fully recognised. The same organism placed in sewage and in chicken broth, reduced in the first instance 0·1 to 0·2. gram of nitre per litre, and in the second instance fifty grams per litre. Some experiments of my own are equally clear on the point. Two equal volumes of diluted urine were taken; one received nitre at the rate of one gram per litre; the other received both nitre and sugar, each at the rate of five grams per litre. Both solutions received 0·5 gram of soil to supply the denitrifying organism. The solutions were then covered with a layer of paraffin oil to exclude air, and thus intensify the action of the organic matter, and were kept at a temperature of 70 degrees Fahr. In the solution containing no sugar a slight evolution of gas occurred, and nitrites appeared in the liquid; some reduction of nitrate thus took place. The action then stopped, and much of the nitrate remained permanently in the solution. In the second case, in which five times the quantity of nitre was present, accompanied by its own weight of sugar, the whole of the nitrate disappeared in eleven days. The presence or absence of sugar thus entirely determined the extent to which denitrification would take place.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book,' containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. 'Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

WORK FOR THE WEEK.

WARM ORCHIDS.

THE days are now lengthening, and the occasional sunshine reminds us of the vast amount of important work to be done. In almost every house there are some plants needing especial and immediate attention. Some require repotting, others top-dressing, &c., and if the summit of success is to be reached then the necessary assistance must be rendered. If a good stock of the best orchid peat has not been obtained, it is quite essential to purchase such forthwith, and also a good stock of teak baskets in different sizes and shapes in order to suit requirements. The pot-shaped baskets are used a great deal, and, generally speaking, are the best. Dendrobiums and cattleyas thrive well in them, as their long roots have something to cling to for a longer period than in the square ones. Phalænopsis will require a slight shading for a short time in the day when the sunshine is rather strong; otherwise they are bound to flag, and the temperature will rise too quickly and fall in a similar way when the sun goes down; it is therefore very important that this point be considered, for spot appears largely as the result of fluctuations of temperature. A slight damping in the afternoon will be required as well as in the morning, balanced with a free circulation of air night and day, wind and weather permitting, the bottom ventilators being left open on the reverse side to the wind, and both sides when fit. Dendrobiums that were removed to a warmer house to flower will now be starting into growth; repotting or rebasketing must be done at once, and after this place the specimens in about 62 degrees of heat for a start, and the watering must be done very cautiously; a slight occasional syringing is very beneficial. Let the stock still resting be examined, and all that are showing signs of growth or that have buds (unless some are being retarded) should be removed to a warmer house—five degrees warmer—in order to start them quietly and bring on the flowers gradually. Young seedlings must be repotted also at this season.

Cattleya labiata autumnalis must now be repotted or top-dressed as required; those that require repotting must be shaken from the old material, and, so as not to injure the roots that cling round the outside of the pot, the pot must be broken; arrange the roots close to the fresh pot, to enable them to have full benefit of the humid atmosphere, at the same time arranging the lead of the plant as near the middle as possible. Crock the pots three parts full and use good fibrous peat, after shaking out all the dust, mixing it with clean green sphagnum, trimming all off nicely with a pair of scissors. Cattleya Trianæ, having passed out of flower, must be served likewise. Cattleya Bowringiana that was not potted earlier must receive immediate attention, taking care that the plants are kept well up in the pot, as they make their growths low down. Angræcum that have finished flowering must also be attended to. Cymbidium Lowianum and its hybrids will now be growing fast and also producing strong spikes, so plenty of water will be needed, and a dose of weak liquid cow-manure will help the flowers, giving them vigour and bringing out the colour; Cymbidium eburneum will require the same care. Lælia anceps are now rooting freely, and a slight syringing among the baskets will encourage these. Fumigating must be done on quiet days, and a keen eye must be kept for scale, using brush or sponge to eradicate it before it becomes established. The phalænopsis house should register 65 degrees by night and 70 degrees by day; cattleya house, 60 degrees by night and 65 degrees by day; intermediate house, 58 degrees by night and 62 degrees by day.—T. STAFFORD, *Tyntesfield Gardens.*

STOVE PLANTS.

IN our stoves the majority of plants will have commenced growth, and if not already done, the necessary repotting should be attended to at once before the sun gains too much power, else flagging and loss of many leaves will be the result. After repotting, watering requires to be done with great care; the fewer applications of water possible, consistent with the welfare of the plant, until the roots are working freely in the new soil, the better. One hears many complaints about the nature of the soil used in many gardens not being suitable for the growth of plants in pots—in many such cases the fault can easily be traced to injudicious use of the watering pot directly after potting—thus souring the soil before it is occupied by active-feeding roots. Large shifts are to be avoided, unless the one in charge can be relied upon to use the water-pot with discretion, else disaster is sure to ensue. Beware of dribblets, which only moisten the surface soil and never penetrate to the lower stratum. In all cases of newly-potted plants defer watering as long as possible, and when it is applied, give sufficient to moisten every particle of soil in the pot. Syringe freely amongst the pots, damp floors and walls, and afford as little air as possible, as by such treatment plants will soon recover themselves, and suffer very little check from the process of repotting. Gloxinias which were started in January should be now well established in five or six inch pots, and showing their flowers; keep them in a light position, and standing on a moist base if possible, they like plenty of moisture in the air, but are better if not syringed overhead; give them an occasional sprinkling of patent manure, they are also partial to an occasional application of soot water, not too strong. Start batches fortnightly, potting them on as required; we use a compost of two parts loam, one part leaf-soil, half a part of cocoanut-fibre refuse and sand, in the case of older tubers a little decayed manure is incorporated. Prick off seedlings of gloxinias as soon as large enough to handle, mixing plenty of leaf-soil and sand in the medium into which they are pricked out. Seedlings of Isolepis gracilis, Cyperus alternifolius, eulalias, &c., are better potted two or three together into thumb pots. If seed is sown now of Panicum plicatum, useful plants for furnishing will be produced by the early autumn; this is a very useful subject for many purposes, not the least being the utility of its foliage for mixing with flowers in large vases in the rooms; it is often mistaken for a slender-growing palm.

Alocasia Lowi, A. Veitchi, and A. metallica are plants of noble foliage, and are striking objects either as permanent occupants of the stove, or for exhibition and furnishing purposes. In potting these avoid soils of an adhesive nature, use a compost of peat, chopped sphagnum, sand, and charcoal; the drainage must be thorough, as when growing they require an abundance of water. Alocasia macrorhiza variegata may be potted in a compost consisting of two parts loam, one part leaf-soil, a little decayed manure, and a good admixture of sand. Justicia carnea, and J. c. rosea are very old occupants of our stoves, and perhaps it is on that account they are so very seldom seen now; at any rate, wherever they are grown they are appreciated. They can be had in flower over the greater part of the year by inserting cuttings at different times. They will root freely in a temperature of 65 degrees, with or without bottom heat; insert the cuttings singly in two-and-a-half-inch pots, shade from bright sun, and give a sprinkle overhead now and again during the day; when rooted shift into six-inch pots, in which they will flower, using for a compost three parts loam, one part leaf-soil, and one half part old mushroom-bed manure with sand added; they are partial to a free use of the syringe. Anthurium Scherzerianum, A. Andreanum, and other kinds, with their quaint flowers, and more or less brilliant colours, are worthy of space in even the smallest stove. During the growing season they delight in copious supplies of water, both overhead and at the roots, therefore, in the first place it is necessary to afford good and abundant drainage, and in the second the compost must be porous to allow the water to pass freely away; good fibrous peat, sphagnum, crocks, charcoal, and coarse silver sand are what they delight in, and if surfaced over with growing sphagnum so much the better. Tubers of Gloriosa superba may be started now, and before starting put them into the pots in which they are to flower, as they are impatient of beirg disturbed during their growing season; use as a potting medium equal parts of peat and loam, with leaf-soil and plenty of sand added; handle the tubers carefully as they are very brittle. Starc fresh batches of caladiums, achimenes, gesneras, &c., and pot on those earlier started as they require it. Allow a rise in the temperature of the stove of 5 degrees, both by day and night, from fire heat, and with the lengthening days the syringe may be used more freely. Keep a sharp look-out for insect pests, and attend to them directly they are seen—not waiting for them to become numerous and cause injury to the plants. Those whose business it is to water the plants should make a point of crushing any mealy bug seen while watering; also, when syringing, bear in mind that the undersides of the leaves are the general hiding places of red spider and thrips, and thus make it a special endeavour to dislodge any lurking there.—J. TUNNINGTON, *Ripley Castle Gardens.*

CONSERVATORY AND GREENHOUSE.

As the sun is gaining power daily no time should be lost in fixing blinds o other means of shading to the different houses where flowering plants are arranged. It is too early in the season to give a permanent shading to the roof, but most of our spring-flowering plants, particularly azaleas, cinerarias, primulas, tulips, and the like retain their true shades of colour, and last much longer in perfection when not exposed to the full force of the sun's rays. Now is a good time to work up a fresh batch of coleus, and as the tops of last year's plants will now be ready for removal, it will be well to obtain the desired number of cuttings at once, and destroy the old stools, as these become unsightly and may encourage the spread of insect pests. The same remarks apply to all plants which have been kept for stock purposes through the winter, as for the next few weeks space will be valuable in all departments.

The present opportunity of dividing and repotting ferns that require it should not be lost. It is almost impossible to have too many plants of Adiantum cuneatum in small pots where there is much decorating, while many of the pterises are equally valuable. To have neat plants, with erect fronds, it is very necessary that the whole of the old frondage be removed before the young ones push through, or the latter will be drawn up weakly. A well-established plant growing in a six-inch pot could be divided into four, and the pieces potted into three-and-a-half or four-inch pots; these make capital material for margins of groups, conservatory stages, or for filling baskets. I never use peat for these plants now, as I find the fronds possess more substance when grown in loam alone. Having potted up a sufficient number, stand the pots close together on a moist stage or bed, give them one good watering, shade them from mid-day sun, and dew them overhead with tepid water morning and evening. Fronds of a pale green colour are generally preferred for use with cut bloom in floral designs, &c., and are obtained by keeping the plants near the glass, and not shading. Of course the atmosphere of the house is kept very moist, and the plants when well established receive abundance of water. Hanging baskets when well furnished make pleasing objects in the conservatory, and for this purpose nothing is better than ferns in variety. We have a couple of baskets of A. cuneatum four feet through. The baskets are made of stout wire, perfectly plain, and form a true half globe. Those with broad, flat bases, or a lot of fancy wirework, should be rejected, as it is difficult to cover them evenly with fronds. Line the inside of the basket with moss—push the pieces of fern through this, about two inches apart, and fill up gradually with chopped turf and broken charcoal. Hang the baskets in a warm close house, and keep them syringed until the fronds meet each other, when this should be discontinued and copious watering afforded.

Clivias have proved most useful throughout the winter in furnishing abundance of flowers, which last quite a fortnight after being cut. These plants deserve more attention than they generally receive. They are naturally late spring-flowering plants, but we find them more useful for mid-winter and onwards, when other things are scarce; we are now dividing and increasing the stock as much as we can. A stiff soil suits the coarse-feeding roots best, such as rather heavy loam, with a little spent mushroom-bed manure and charcoal. The newly-potted plants should be kept together by themselves, and not stood about in cold dry houses, or under the stages as they are sometimes found. Sow seed of mignonette in small pots to provide useful material for filling window boxes and the like later on.—RICHARD PARKER, *Goodwood Gardens.*

THE FLOWER GARDEN.

THE potting-off of all bedding pelargoniums wintered in boxes or store pots should be finished within the next few weeks. Pots of the size usually known as large sixties are the most suitable, and the soil for potting should not be too light, especially for the stronger growing varieties, but for the variegated and more delicate ones that of a lighter nature may be used. No crocks should be placed in the pots, as these are a nuisance when turning out at bedding time; a small portion of half-rotten leaves placed in the bottom of each pot will afford ample drainage. A little extra heat should be given, and an occasional syringing over on bright days, until partially re-established. Where desired to increase any variety, the tops should be inserted in boxes or pots and stood in a warm house. Old plants may also be placed in heat for the production of cuttings, and this will apply also to store plants of coleus, alternantheras, and ageratums for the furnishing of quantities of cuttings in a few weeks' time. Old roots of cannas used in the flower garden should now be examined, and if desired to increase the number the rhizomes may be cut up into pieces with one or more eyes to each, and be potted up into forty-eights or thirty-two sized pots. The older portions should be rejected. After potting stand in a warm house until they have started well into growth. Where seedling verbenas are used for bedding the seeds should be sown forthwith. These seedlings form excellent material, and beds filled with them in mixed colours are effective, and, providing the seeds are from a good strain, the flower trusses are larger and the growth more free than from plants increased from cuttings. Verbena seeds should be sown in shallow pans or boxes filled with any moderately light soil pressed down firmly, scattering the seeds thinly over the surface and just covering with a little finely-sifted soil. If placed in a house or pit with a temperature of 60 degrees, germination will follow in about fourteen days, when the seedlings should be sifted into a cooler house. As soon as large enough to handle they should be pricked off into other boxes two or three inches apart, and when established, gradually hardened off in a cold frame. Antirrhinums and pentstemons may be raised and treated in a similar manner, but these, especially if required in quantity, may be pricked off direct into a cold frame, and from thence transferred to the beds or borders. The former may now be obtained in distinct colours of white, yellow, crimson, and other shades and in strains, the height of which may be from eight to eighteen inches when in bloom. Antirrhinums are excellent dry-weather bedding plants, and may be used for massing in beds or filling up spare spaces in the herbaceous borders.

Hollyhocks, which, owing to the disease that has been prevalent for some years past, have somewhat fallen out of cultivation, but are easily raised from seed, and healthy plants for the year, at least, may generally be ensured if raised in this way. This fine old showy perennial is a grand subject for the back part of herbaceous beds or borders, and a cheap way of raising a stock is from seed. They should be treated much as detailed above for verbenas, as regards sowing but pot up the seedlings into small pots as soon as large enough, and after growing on in an intermediate house until established, transfer to a cold frame, which should be kept close for a few days. Pot on into five-inch pots, and by the middle or end of May strong specimens should be ready for turning out into the borders, and with good cultural attention after will produce fairly strong spikes of bloom this season. Herbaceous borders should now be lightly forked over, turning in any manure placed over the surface early in the winter or added now. Although deep digging about these established borders should never be done, pointing over carefully with flat-tined forks for the sake of tidiness is advisable annually in early spring. The young growths starting from choice delphiniums in these borders should be protected from slugs by having ashes or a little soot scattered about them. Where desired to increase any choice varieties of the latter, this may easily be done now by taking off the shoots, starting from the base of the old stools. These, if detached without roots and potted up singly into small pots, using sandy loam and leaf-soil, and stood in a cold frame, will soon form roots and make good plants for placing in the borders in a couple of months' time. When propagated in this way the most may be made of any new varieties, and if treated liberally, the young plants will produce fairly good spikes of bloom this season. In the pleasure grounds, lawns should be kept well swept and rolled as, owing to the mild weather, mowing will be necessary early this year.—C. HERRIN, *Dropmore Gardens.*

HEDGES: THEIR FORMATION AND MANAGEMENT.

UNLESS in the case of the various railway companies and the owners of a few large properties, the management of live fences in this country is sadly neglected, a fact that is forcibly brought home to the observant traveller in almost every part of the kingdom. Agricultural depression and the consequent low state of the farmers' funds have, no doubt, much to answer for in this particular, while not a little is attributable to the want of a thorough knowledge not only of the formation but after-management of these as well. Practically speaking, hedges may be divided into two classes—useful and ornamental—or, in other words, such as are employed for purely protective purposes, and such as find a place on the lawn, the pleasure ground, and in the garden, and where ornament more than any specially useful object is of first consideration. For farm or woodland purposes the quick or hawthorn, the beech, hornbeam, and holly are the only plants that have been found sufficiently thick, strong, and impenetrable to live stock; while where ornamental qualities are desired almost any shrub can be utilised that fancy dictates, special mention being made of the yew, box, privet, several kind of berberis, and some of the low and compact-growing thuyas aud cypresses.

The preparation of the ground is a most important operation in connection with the formation of live fences, and one that should never be passed over, either on the pretext of time or expense. Thoroughly trench the ground to a depth of not less than two feet and about four feet in width, turning the soil loosely up to the ameliorating effects of the weather, and if this work can be performed a couple of months before the plants are to be inserted so much the better. Where the soil is poor and light a heavy dressing of thoroughly decomposed farmyard manure will have the effect of causing the hedge plants to grow away freely and strong, but such should be thoroughly incorporated with the soil and applied at time of trenching. As it is advisable, particularly if the situation is at all damp or the soil of a heavy retentive nature, to plant rather above than below the general ground level, a low mound should be formed along the intended line of fence when trenching the soil, such assisting materially in keeping the plants from excessive moisture and likewise aiding in the clearing and after-management of the fence. Sometimes it is found necessary on low-lying ground to cut a ditch along the side of the contemplated line of hedge, the soil so removed being utilised in forming a dry bank or ridge on which the plants are placed.

Planting should be performed in autumn or immediately after the fall of the leaf, and should on no account be left to a later date than the end of February, the quick being one of our earliest shrubs to start into growth. The plants should be stout, stocky, and of four years' growth. The size of the thorns is of more importance, however, than the age, and those rather thicker than a pipe-stem, though short in proportion, are infinitely preferable to others of taller and lankier growth. When planting stretch a garden line along the prepared ground, and take out a trench of sufficient depth and width to allow of the roots of the quicks being spread out to their full extent. The plants should be placed upright, six inches apart if in single line, and nine inches apart if in double line, and not deeper in the ground than they stood whilst in the nursery, the conspicuous mark on the bark of the stem clearly pointing out the depth to which they should be inserted in the soil. Fill in the finest soil next the roots and tread firmly, keeping the plants as equidistant and upright as possible. It is not unusual to plant the quicks in double line, but with strong plants on well-prepared land a single line is to be recommended, many of our finest fences having been so formed. Cutting or hedging back the newly-planted thorns, so as to induce stout and thick bottom growth, is often successfully adopted, and especially when the plants are tall and weak of growth. The beech wants the rigidity of the thorn, but is better as a shelter plant, retaining, as it does, a great proportion of its leaves during winter. It also succeeds on chalky soil and on exposed ground at considerable elevations. The hornbeam is another useful hedge plant that succeeds well in fairly rich soils and when not too exposed.

The pruning and after-management of a hedge are of much importance, but unfortunately, too often lost sight of. A yearly clearing away of all bottom growth of rough-growing weeds should never be neglected, while equally, if not more important, is an annual cutting back of the young shoots, and which above everything else maintains that rigidity and closeness of growth which are all important for either farm or plantation hedges. Ivy and elder are highly injurious to every kind of live fence, and should be at once removed; while nettles and strong-growing grasses also act in a pernicious manner by depriving the hedge plants of their sustenance. In pruning a fence, be it of whatever kind, the switching knife is to be alone recommended, shears making jagged cuts and loosening the bark below the points of amputation, thus retarding fresh growths to a great extent. The switching or pruning knife should be of the most approved make and kept well sharpened, such an instrument in the hands of a skilled hedger turning out very commendable work. Pruning may be engaged in at any time after the fall of the leaf, but it is advisable not to prosecute such work during severe frost.

A. D. WEBSTER.

EXHIBITIONS AND MEETINGS.

SHIRLEY GARDENERS' ASSOCIATION.

THE monthly meeting was held at the Parish Room, Shirley, Southampton, on the 21st inst., when the president, Mr. W. F. G. Spranger, presided over a fair attendance of the members. Mr. E. T. Mellor, B.Sc., London, lecturer in Biology to the Hartley College, Southampton, gave his second and concluding lecture on "Fungi." He said the injurious parasitic fungi were stated by a recent authority to number 1,600 species. Taking Perenospora infestans as a typical example of this class, he by means of lantern slides traced the life history of this troublesome pest, showing also how resting spores, to enable the plant to get through the unfavourable winter, were produced, and urging on his hearers the necessity of destroying by fire all garden refuse for this reason. Rust on cabbages and rust on wheat were also glanced at, the lecturer stating that Australia lost in one year £2,500,000 through the latter. The beneficial fungi were not so numerous, and there was only time left to consider that which exists on the roots of all leguminous plants, looking like tubercles. These were able to take up nitrogen from the air passing it along to the plants, which were thus enabled to live on very poor soil.

A brief discussion ensued, and at the close a hearty vote of thanks was accorded to the lecturer, and also to the president for conducting the business of the evening.

ROYAL GARDENERS' ORPHAN FUND.

AT the annual general meeting of this admirable charity held at Anderton's Hotel, Mr. W. Marshall presided over a moderate attendance. Among those present we noticed Dr. Masters, Messrs. Bates, Gordon, Lyne, Poupart, Barron, Cummins, Wynne, Roupell, Walker, Jones, Assbee, Osman, Outram, R. Dean, McLeod, Reynolds, J. Fraser, May, Cuthbert, H. J. Veitch, and Melady.

The proceedings were of a purely formal character, as no questions were asked or raised. After the reading of minutes, &c., by Mr. Wynne, the report, taken as read, was as follows:—

Annual Report.

The Executive Committee, at the close of the tenth year of the existence of the fund—it having been established in 1887—can look back with pride and satisfaction upon the substantial progress made during that decade. The Royal Gardeners' Orphan Fund is now firmly established among gardening institutions, and during the period of its operations, while it has succoured a large number of orphan children, all of them in necessitous circumstances, it has also been able to invest a small reserve fund. Your committee feel they can heartily congratulate all those constant and earnest supporters of the fund, who, since 1887, have rendered such valuable and acceptable aid.

In submitting their annual report and financial statement, your committee have to record with some feelings of regret, that the receipts for the past year have not been so satisfactory as could be desired, and would therefore urge upon the friends of the charity the necessity of increased efforts during the ensuing year. One very gratifying feature has to be recorded. The receipt of letters of deep thankfulness from the mothers and guardians of children who have ceased to be chargeable to the fund, owing to the operation of the age limit. One mother, after expressing her sense of most timely help, observes: "I sincerely hope that my children may help the fund as they have been helped by it." Besides the ordinary payments of the sum of five shillings per week to orphan children, your committee have made special grants in necessitous cases to children on leaving school, or being apprenticed to some trade, thus giving them a start in life. The sum of £22 10s. has been expended in this helpful way during the year.

During the past ten years, ninety-eight children have derived benefit from the fund; of this number, sixty-two are now receiving a weekly allowance. This number will be increased by those fortunate enough to secure election to-day. The total amount paid to children since the fund was instituted is £5,807 5s. Another most gratifying circumstance is the amounts received from collecting boxes, the proceeds of concerts, sales of flowers, &c., at provincial flower shows. Among the most important donations are those of £50 from the Scottish Horticultural Association, part of the proceeds of the magnificent exhibition of chrysanthemums held in Edinburgh, in November last, and £26 5s. from the Royal Caledonian Horticultural Society. The Chislehurst Gardeners' Society have contributed £23 12s. 6d., and the Altrincham Gardeners' Society £18 8s., proceeds of concerts. Smaller sums from other societies have been received and proved equally acceptable; such receipts have now become an important source of income, and your committee tender their most grateful thanks to all who have so materially helped to swell the resources of the fund. The sum of £457 5s. 11d. has been received as a bequest made by the late Mr. J. W. Thomson, of Hayward's Heath, formerly a well-known nurseryman, and invested in accordance with the terms of the will. This legacy will henceforth be known as the "J. W. Thomson Trust."

The annual dinner held at the Hotel Cecil in April last, was presided over by Sir J. Whittaker Ellis, Bart., and resulted in a handsome subscription list of £635. Your committee owe a great debt of gratitude to Sir J. W. Ellis for his very able advocacy of the objects of the fund, and tender him their most hearty thanks. The best thanks of the committee are also due to the treasurer, N. Sherwood, Esq., for the warm interest he takes in the fund, and his faithful discharge of the duties of the office he holds; also to their auditors, Mr. M. Rowan and Mr. P. R. Barr, for their labours in auditing the accounts. The retiring auditor is Mr. M. Rowan, who is nominated for re-election. The committee have to deplore the loss by death of Dr. Robert Hogg, one of the vice-presidents from the commencement of the charity; and also of an able colleague, Mr. W. G. Head, an active supporter of the fund, and so long associated with the Crystal Palace at Sydenham. Mr. G. Cuthbert, of Southgate, has been elected in his stead. The members of the Executive Committee, who retire by rotation, are Messrs. Assbee, Ballantine, Cannell, Cummins, Gordon, McLeod, Roupell, and Wynne, all of whom offer themselves for re-election, with the exception of Messrs. Ballantine and Cannell, who retire, Mr. A. Outram and Mr. G. H. Richards being nominated to succeed them. Mr. A. F. Barron is again nominated as secretary, at the same remuneration.

The Chairman, in moving the adoption of the report, remarked that he had no observations to make concerning it. As a private member, he remarked that he should like to see the committee in future consider the question of allowing or not allowing two orphans from one family to appear as candidates or to be both elected to the benefits of the fund. The motion was carried unanimously. Mr. Poupart then proposed a vote of thanks to their treasurer, Mr. N. N. Sherwood, remarking that the fund was fortunate in having the services of such a gentleman; seconded by Mr. Osman and carried. Mr. R. Dean moved that the meeting's thanks to Messrs. Rowan and P. R. Barr be given for their services as auditors. This was carried without dissent. The Chairman proposed the re-election of Messrs. Assbee, Cummins, Gordon, McLeod, Roupell, and Wynne as members of the committee. This was carried, as also was the proposition that Messrs. Outram and Richards be elected on the committee in the places of Messrs. Ballantine and Cannell, who retire. Mr. Marshall then moved the re-election of Mr. A. F. Barron as secretary of the fund, and spoke highly of the services rendered by him. This motion was ably seconded by Mr. J. Walker and unanimously carried. The scrutineers of the ballot, proposed by Mr. H. J. Jones and approved, were Messrs. H. B. May, R. Dean, J. McLeod, and J. Walker. The annual meeting occupied about half an hour, and then the members parted to await the result of the ballot.

(Signed) P. RUDOLPH BARR } Auditors.
M. ROWAN

Dated January 22nd, 1898.

The result of the election was announced at a quarter to five, when the following ten children were placed on the funds of the charity: Agnes Macintosh, Edinburgh, 349 votes; Robert John Smith, Salop, 332; Jamesina Baird, Stobo, N.B., 278; Lydia Annie Milne, Westmoreland, 275; Hermine Kosbab, Twickenham, 272; William Ewart Holmes, 269; Ruth Amy Worth, Liverpool, 241; Margaret Annie Richardson, Cheshire, 232; Constance Mary James, Southampton, 209; and Annie Kathleen French, Lingfield, 166. The latter was placed on the funds as the recipient of the Thomson Memorial Bequest. The total number of votes polled was 3,157. Votes of thanks to the scrutineers and chairman concluded the business of the annual meeting.

Friendly Dinner.

An informal friendly dinner took place at half-past six at Anderton's Hotel, Fleet Street, at which those members and friends of the orphan fund, already mentioned, were present, and also Messrs. J. H. Veitch, Sherwood, Miles, J. H. Laing, J. G. Ingram, D. B. Crane, and Mason, &c. Owing to illness, Mr. P. C. M. Veitch was unable to be present, consequently the chair was taken by Mr. N. N. Sherwood.

After dinner and the usual loyal toasts, the Chairman proposed "Continued Success to the Royal Gardeners' Orphan Fund." He regretted the absence of Mr. P. C. Veitch, and especially the cause of his absence. He referred to the fine speech made at a similar gathering a year previous by Mr. Owen Thomas, in which the latter hoped for a record year to the fund as a memento of the Diamond Jubilee of Her Majesty. He was sorry to say that hope had not been realised, for though they had done fairly well, 1897 was not a first-rate year for the charity in which they were all interested. They were all proud of the ten years' progress of the fund, of the fact that sixty-two children were being helped by it, and that since 1887, £5,807 had been spent for the direct benefit of gardeners' orphans. They had close on £9,500 invested, but he, as treasurer, would not be satisfied until that sum had been increased to £20,000. The Chairman spoke highly of the energy displayed by some local secretaries and societies in helping the fund, making special reference to the Scottish Horticultural Association, Caledonian Horticultural Society, and the Chislehurst and Altrincham Gardeners' Associations. He also referred to Mr. H. J. Jones, whose collecting card contained an enormous number of names, and to Mr. Miles, who in the Southampton district had enlisted fifty-five new subscribers. All associated with the fund felt a great responsibility, and they wished such a feeling would extend more widely among the gardeners of the kingdom, for if such were the case it would follow as a matter of course that employers and traders would also do their best to assist the cause. The toast was duly honoured, and responded to by Mr. W. Marshall, the latter observing that he considered that the most deserving candidates had been elected.

Mr. Poupart directed the musical programme for the evening, the contributors being himself, Messrs. Mason, D. B. Crane, H. J. Jones, and A. H. Weeks. Votes of thanks to Mr. Poupart, to Mr. Barron, and to the chairman, brought a pleasant evening to a conclusion.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates.

Chrysanthemum Red L. Canning.—G. D., Cardiff: The address, given in a recent issue, of the holder of the stock of this chrysanthemum should have read Walton-on-Thames, instead of Henley-on-Thames; Mr. Felgate's establishment is Bushill Road Nursery in that town.

Heating Small Greenhouse.—E. A., Birmingham: There are now very many first-rate oil stoves on the market which would prove suitable for heating your small greenhouse. They are provided with a radiator, so that all the heat created is made the most of. Then also the newer stoves, especially those supplied by firms who make a speciality of heating apparatus and advertise in our columns, are so constructed that if properly managed no offensive odour is given off. An application to any of the makers would put you in possession of price lists.

Infested Apple Trees.—C. M., Romsey: The pieces of apple wood sent contained no beetles, but the borings were such as might have been produced by the Apple Bark Beetle (*Xyleborus dispar*). We scarcely think this is the beetle that has done the damage, however, for it does not confine its operations to dead wood, but rather attacks young trees, frequently killing them. If you can catch a few beetles on the trees send them along in a close-fitting tin box. Meanwhile, as only the dead wood is attacked there is not much to complain of, and the best thing to be done is to remove every scrap of dead wood from the trees before the buds on the live growth are further forward. Remove all dead and loose bark, and then limewash the trunk and main stems so as to kill moss and lichen. If liquid manure is to be obtained from farmyard or stable cesspools give the trees a good dose now, and repeat the operation on several occasions during the season of full growth, more especially after the fruits have begun to swell.

Caladiums and Fuchsias.—W. M. P., Elcombe: A dozen good caladiums are Baron Adolphe de Rothschild, Charlemagne, Chelsea Gem, [illegible], Nain Rouge, Lord Rosebery, John Peed, Mrs. Harry Veitch, Mons. [illegible], Reine de Danmark, Mons. Chater, and John Laing. Two small growing sorts that are fine for grouping, &c., are Argyrites, and Minus erubescens. Twelve good fuchsias will include Abundance, Lye's Rival, General Roberts, and Lord Falmouth as dark varieties; Beauty of Lavington, Eynsford Gem, Lye's Perfection, and Princess May as light forms; Duchess of Edinburgh and Miss Lucy Finnis as white double forms; and Alphonse Daudet and Phenomenal as dark [illegible] varieties.

Cucumbers.—W. W., Norwich: If you will state the particular points upon which you wish special information we shall be pleased to help you. You probably cropped your cucumbers too severely and failed to apply occasional top dressings of rich soil or give frequent supplies of liquid manure. Plenty of heat and moisture are necessary for cucumbers; they require very little shading even in the brightest weather, but they need fresh air as often as it can be admitted without risk. Cut out old growth as soon as it can be dispensed with and encourage young shoots to fill the space and produce fruits. Cut cucumbers as soon as fit, so as not to strain the plants more than can be helped; stand the cut ends in a shallow dish of water and the fruits will keep fresh some time. Let the water for syringing or watering stand in a tub or tank in the house long enough before use to become warmed.

Liquid Manure from Stables.—H. H., Faringdon: The liquid, composed of the urine of horses and the water used in washing out the stables, &c., will prove valuable for applying to fruit trees, roses, and all gross-feeding plants, including numerous kitchen garden crops. If you can obtain such liquid in quantity you are in a better position to withstand drought in the garden than many growers. It is probable that no addition of clear water will be necessary, but this you will be best able to judge from a knowledge of the number of horses stabled and the amount of water used for swilling. If at all in doubt as to the strength of the liquid apply some first by way of experiment to some plant or plants, remembering that established fruit trees, roses, vines, &c., may be given fairly strong liquid manure owing to the amount of soil through which the roots penetrate.

Manure for Oats.—H. F., Annesley: It is apparent that the land is very poor, and there is a great need for adding organic matter to it, so that it will the better hold moisture, and give the oats or other crops something substantial to work upon. So far as we are able to judge from your letter the land will be of little value for producing good crops until a good dressing of stable and farmyard manure, separate or mixed, is applied to it. The best artificial manure to use with oats is superphosphate of lime at the rate of two to three hundred weight per acre. When growth has made some advance it is desirable to give a top-dressing of nitrate of soda at the rate of three-quarters to one-hundred weight per acre. Potash in some form would prove a suitable manure for such land, but potash manures, such as muriate of potash, is best applied in the autumn, so as to be available for the plants' use in spring and summer.

Employment at Kew.—R. O., Drumrauck: Judging from the number of queries we have received during the past twelve months, there is a growing desire among young gardeners throughout the country to graduate at the Royal Gardens, Kew. This is not surprising considering the large number of good positions held by old Kewites throughout the world. To gain employment at Kew, the candidate must be of average height and physically sound. The authorities evidently consider the fact of application as evidence of soundness of mind. The

SELECT NOVELTIES IN SEEDS FOR 1898.

TO BE HAD FROM ALL SEEDSMEN.

BURPEE'S NEW DWARF SWEET PEA, PINK CUPID.

We call special attention to this unique Novelty of American origin. No Novelty of recent introduction has such brightness, beauty and grace combined as PINK CUPID.

Packets of 24 seeds, each 1/-; Packets of 12 seeds, each 8d.

EVERLASTING PEA, PINK BEAUTY (Lathyrus latifolius var.)

An entirely new variety, the colour of which is a delicately shaded pink on the standard, the lacing of the edge being paler than the centre, the wings are deeper pink, of a very rich shade, giving it a very striking appearance. **Per Packet, 1/-.**

PRIMULA FIMBRIATA ROSEA DELICATA.

The colour of this beautiful new variety is a charming and delicate shade of rose-pink. The flowers are large and well fringed, whilst the eye is a bright yellow, showing a striking contrast to the ground colour of the petals. **Per Packet, 3/6.**

NEW CULINARY PEA, HURST'S RELIANCE.

The finest of all second early kinds. **Per Quart, 2/-.**

NEW CULINARY PEA, CAPTAIN CUTTLE.

This superb Pea, growing about 3½ ft. high, is the result of a cross between "G. F. Wilson" and "Evolution." It is a most robust growing sort, and on that account should be sown thinly. The pods are large and handsome, terminating in an abrupt hook, and contain from seven to [illegible] very large deep green peas of excellent quality. It is undoubtedly one of the heaviest croppers in existence. Awarded full marks of merit by the Royal Horticultural Society. In **sealed Half-pint Packets, 2/6 each.**

NEW CULINARY PEA, THE GLADSTONE.

In Half-pint Packets, 2/- each.

MELON, DIAMOND JUBILEE.

First Class Certificate, Scottish Horticultural Society, August 3rd, 1897.

This variety is the result of a cross between "Best of All" and "Countess," and is a decided improvement on both these well-known kinds. The fruits are oblong in shape, beautifully netted, and assume a pretty golden-yellow when ripe; weight from 3 to 5 lb., flesh greenish-white, flavour excellent, a distinct acquisition for early crops, and will prove a boon to market growers. **Per Packet, 1/6.**

Wholesale only from HURST & SON, 152, HOUNDSDITCH, LONDON, E.

COMPETITION DEFIED!

OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

FLORIST'S FLOWERS and HARDY BORDER PLANTS

is got up REGARDLESS of TROUBLE or EXPENSE [illegible] the result that it is by UNANIMOUS CONSENT [illegible] the most COMPREHENSIVE, most ACCURATE [illegible] RELIABLE, most COMPLETE, and BEST EXTANT [illegible]

It gives full and ACCURATE DESCRIPTIONS [illegible] thing in the way of FLORIST'S FLOWERS, [illegible] HEIGHT, TIME of FLOWERING, and PRICES [illegible] best HARDY BORDER PLANTS, together [illegible] ENGLISH or COMMON NAMES, and a [illegible] VALUABLE INFORMATION that cannot be had [illegible]

It is, in fact, a veritable REFERENCE-BOOK, [illegible] to all growers of these plants, and should be in the [illegible] intending purchasers. Free on application.

JOHN FORBES, Nurseryman,

HAWICK, SCOTLAND.

ESTABLISHED 1870.

FOR SALE, large number of good [illegible] hand and new wrought and cast iron and wood [illegible] all shapes and all sizes; lists and prices on application; [illegible] solicited; tanks of all kinds bought.

Apply THOS. W. WARD Fitzalan Chambers, [illegible]

you must be able to show that for at least five years you have been employed in good gardens or first-rate nurseries. Suitable references should be forthcoming, or, at least, copies of them should be sent with a letter of application for employment addressed to Mr. G. Nicholson, Curator, Royal Gardens, Kew, Surrey. If the application is entertained a form will be returned to you to fill up, and on this being sent back to Kew your name will be placed on the register, and all you have to do is to wait patiently until a vacancy occurs. This may happen within a few days, or it may not happen for a month or two. The candidate must be twenty-one years of age.

Names of Plants.—I. C., Bath: Lælia Lindleyana, a curious species.

M. F. E., Egham: 1, Selaginella Mertensi; 2, S. flagellifera; 3, Davallia bullata; 4, Nephrolepis exaltata; 5, Begonia ascotiensis; 6, send when in flower.

W. M. P., Elcombe: 1, Phlebodium aureum; 2, Nephrodium molle corymbiferum; 3, a polypody, send fertile frond; 4, Adiantum formosum.

K. B., Henley: If you will send another set we will do our best to identify your plants, as on former occasions. The last lot became shrivelled before we were able to institute comparisons.

Names of Fruits.—H. G., Isle of Wight: We do not recognise the apple sent, and feel sure it is not Goodwood Pippin. However, if you send a fruit to Mr. R. Parker, Goodwood Gardens, Chichester, Sussex, he will decide. This will save time, and in the meanwhile we will submit the fruit we have to some expert pomologists, and endeavour to find whether the variety is known. An apple that will keep sound and fresh as late as you mention, in the extreme south, is of value, and we should be obliged for further particulars.

"THERE IS NOTHING NEW UNDER THE SUN" is a saying credited to a variety of illustrious authors, from the time of Solomon to the present day. It is a fact that many inventions looked upon as modern are of ancient origin. The telephone, which recently caused such a furore of excitement, was in ancient days a means by which the high priests worked upon the credulity of their disciples. The Pyramids of Egypt and other wonders prove that this generation has a great deal to learn. Holloway's Pills and Ointment, however, were not anticipated by our forefathers, and to-day they stand alone as the best cure the world possesses for all the ills that humanity is heir to.—[ADVT.]

MARKETS.

Covent Garden.

SUPPLIES of fruits are very short, consequently prices have an upward tendency, as the demand is good. Green vegetables are moderately plentiful, but prices are firm. Potato trade quiet, though there is a brisk demand for new. Cut flower trade moderate.

FRUIT.—English grapes, 1s. 9d. to 3s. per lb.; Almeria, 10s. to 20s. per barrel; American and Nova Scotian apples, 12s. to 30s. per barrel; French pears, 5s. to 7s. 6d. per crate; pineapples, 2s. to 6s. 6d. each; bananas, 4s. to 9s. per bunch; English tomatos, 6d. to 10d. per lb.; Canary 1s. to 1s. 6d. per tray, 3s. 6d. to 4s. 6d. per case; lemons, 8s. to 16s. per case; Valencia oranges, 9s. to 18s.; Jaffas, 8s. to 11s. 6d. per box.

FLOWERS.—Arums, 2s. to 3s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 6s. to 9s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 2s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s. 3d.; and tuberoses, 6d. to 9d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; chrysanthemums, 9s. to 18s.; marguerites, 2s. to 4s.; white narciss, 2s. 6d. to 5s.; narciss, various, 1s. 6d. to 3s.; Roman hyacinth, 4s. to 9s.; daffodils, 5s. to 8s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 6s. to 8s.; and violets, 9d. to 4s. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—English onions, 6s. to 7s. per cwt.; Valencia, 7s. to 9s. per case; cabbages and savoys, 4s. 6d. to 6s. per tally; Italian cauliflowers, 2s. 9d. to 4s. per basket; seakale, 10s. to 15s. per dozen punnets; Brussels sprouts, 2s. to 3s. per bushel; French asparagus, 4s. to 7s. 6d. per bundle; mushrooms, 6s. to 8s.; eschallots, 2s. to 2s. 6d. per 12 lb.; French lettuce, 1s. to 1s. 3d.; endive, 1s. 4d. to 1s. 8d.; spinach, 2s. to 2s. 6d. per bushel; parsley, 1s. 6d. to 2s.; carrots, 2s. to 3s. per dozen bunches; celery, 6s. to 12s. per dozen rolls; forced rhubarb, 1s. 6d. to 2s. 6d. per dozen bundles; Malta new potatos, 18s. to 20s.; Algiers, 20s. to 25s.; Canary 15s. to 18s. per cwt.

Borough Potato Market.

Supplies are so large, and the demand so moderate, that there is a prospect of a drop in prices.

Dunbars, 110s. to 120s.; Hebrons, 85s. to 100s.; Snowdrops, 80s. to 90s.; Bruce Maincrop and Sutton's Regents, 80s. to 85s.; Reading Giants and Saxons, 80s. per ton; Belgians, 3s. to 3s. 6d.; Germans, 3s. 6d. per bag.

TONBRIDGE, KENT.

SUMMER CLOUD.
ELLIOTT'S New Shading for Glass Houses.

TRADE MARK—No. 14,629.
Sold in Packets, 1/- each, and in Bags, 7 lbs., 10/6; 14 lbs., 20/-

IT combines efficiency with appearance, convenience with economy, and its effects are lasting. It is easily removed when necessary with hot water. It can be supplied either pale green or grey.

Beware of spurious imitations, which are offered through the success obtained for many years by Elliott's "Summer Cloud" Shading, and see that in ordering you get the "Summer Cloud," which is the only original and bona fide article, with the Trade Mark on each packet.

To be had of Seedsmen and Florists. Manufacturers—
CORRY AND CO., LTD., FINSBURY STREET, LONDON.

CHOICE NEW CHRYSANTHEMUMS.—Well-rooted plants of Master H. Tucker, Duke of Wellington, G. J. Warren, Julia Scaramanga, Lady Hanham, Joseph Brooks, John Neville, Lord Justice Lopes, Mrs. G. W. Palmer, Royal Standard, Madame Philippe Rivoire, Western King, and many other novelties, at moderate prices. List free.
J. SPINK, Summit Road Nursery, Walthamstow, E.

SEED LIST
(Free on Application).

FEATURES.
Alphabetically arranged.
Best sorts, in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.
Many hints and recipes for cooking and serving the various vegetables.
Directions for the storing and forcing of vegetables.
Medicinal qualities of many vegetables and herbs.
Prizes of £5, £3, two of £2, and £1 offered for Photographs of Horticultural Subjects (see page 2 of Catalogue).

THE LIST, containing 93 pages, and a profusion of illustrations, shows (A) What to Grow; (B) How to Grow it; and (C) What to Do with it when Grown; and has been described by an agent on one of the largest estates in England as a BOOK OF REFERENCE.

Another Customer, testifying as to quality, writes: "I should like to add that all the Seeds, &c., purchased from your establishment during the past 14 years have been of the very best quality, and have given great satisfaction."

SHOREDITCH, LONDON.

The Beauty of an English Garden is a

GOOD LAWN

Yet how often one sees poor yellow, moss-grown spaces in place of green, velvety turf. The cause is poverty, constant mowing, and nothing done in the way of restoring the exhausted fertility. Stable manure is an eyesore on a neat Lawn, but

PEARSON'S CHEMICAL MANURE

may be applied with little trouble or expense, and is washed in by the first shower. Will not burn the grass as some compounds do. Apply 2 oz. to square yard any time from now to end of March, 14 lbs., 4s.; 28 lbs., 7s., in Tins. ½ cwt., 12s.; 1 cwt., 20s.

TESTIMONIALS FREE.
Half-cwt. and upwards Carriage Paid to any station.

J. R. PEARSON & SONS, CHILWELL, NOTTS.

Ask your Nurseryman or Seedsman for

RICHARDS' NOTED PEAT.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

Tanned Netting, Bamboo Canes, &c.
Greenhouse Blinds a Speciality.
JOSEPH COOKSON, Manufacturer, Wellington Mills, Liverpool Road, Manchester.

SUTTON'S BEAUTIFUL FLOWERS.
CINERARIA STELLATA.
A charming new flower, raised from a cross between our greenhouse Cineraria and the old C. cruenta. The small starry flowers are borne in loose panicles, which are most graceful for table decoration either in pots or cut for vases. The range of colour approaches that of the ordinary Cineraria. This new flower will become quite as popular as is P. stellata among primulas. Per packet, 5s.

SUTTON'S SEEDS, GENUINE ONLY DIRECT FROM SUTTON AND SONS, THE QUEEN'S SEEDSMEN, READING.

KELWAY'S MANUAL OF HORTICULTURE, the best, largest, and most complete Plant, Seed, and Bulb Catalogue is a veritable Gardener's Companion. 200 large pages devoted to the Garden, include the best of everything.

IMPORTANT AUCTION SALE.

MR. WILLIAM BULL, having disposed of the Ground of his Branch Nursery in the Ashburnham Road, Chelsea, for Building, the land must be cleared by Midsummer. The whole of the contents, therefore, of Twenty Houses, including—

THOUSANDS OF CHOICE ORCHIDS,

WILL BE SOLD BY AUCTION, ON THE PREMISES, BY

MESSRS. PROTHEROE & MORRIS,

OF CHEAPSIDE,

WITHOUT THE LEAST RESERVE.

There will be FOUR DAYS' SALE of ORCHIDS, on

MARCH 28, 29, 30, and 31,

All to be Sold absolutely Without Reserve; to be followed by a Sale during the last week in April of—

THOUSANDS of CHOICE STOVE, GREENHOUSE, and HARDY PLANTS,

SPECIMEN PALMS, AND OTHER ORNAMENTAL PLANTS,

SUITABLE FOR LARGE CONSERVATORIES, WINTER GARDENS, &c.

The Houses, Boilers, and Hot-water Pipes will be Sold on the Last Day of the Sale in April.

A CATALOGUE OF THE ORCHIDS is NOW IN PREPARATION, and will be READY SHORTLY.

As all the Houses and Ground must be cleared, this Sale, being Without Reserve, presents an unique opportunity of acquiring Orchids, New and Rare Plants, and Specimens for Greenhouse and Conservatory Decoration.

Business will be carried on at MR. WILLIAM BULL'S ORIGINAL ESTABLISHMENT FOR NEW AND RARE PLANTS, 536, KING'S ROAD, CHELSEA, LONDON, S.W., as usual.

NEW CARNATIONS.

TREE OR WINTER-BLOOMING VARIETIES.

W. J. GODFREY has pleasure in calling attention to his novelties for this season. They are the result of several years' careful hybridising and selection, and will prove the greatest advance yet made in this section.

The blooms are larger, and of better form than most other varieties, whilst the colours are distinct and beautiful. The habit of the plants is robust and healthy. DESCRIPTIVE LIST POST FREE.

W. J. GODFREY, EXMOUTH, DEVON.

COMPETITION DEFIED!

OUR UP-TO-DATE SEED CATALOGUE

For 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

☞ *ALL FLOWER SEEDS CARRIAGE FREE.*

Packets of 24 seeds, each 1/-; Packets of 12 seeds, each 8d.

EVERLASTING PEA, PINK BEAUTY (Larhyrus latifolius var.)

An entirely new variety, the colour of which is a delicately shaded pink on the standard, the lacing of the edge being paler than the centre, the wings are deeper pink, of a very rich shade, giving it a very striking appearance. **Per Packet, 1/-.**

PRIMULA FIMBRIATA ROSEA DELICATA.

The colour of this beautiful new variety is a charming and delicate shade of rose-pink. The flowers are large and well fringed, whilst the eye is a bright yellow, showing a striking contrast to the ground colour of the petals. **Per Packet, 3/6.**

NEW CULINARY PEA, HURST'S RELIANCE.

The finest of all second early kinds. **Per Quart, 2/-.**

NEW CULINARY PEA, CAPTAIN CUTTLE.

This superb Pea, growing about 3½ ft. high, is the result of a cross between "G. F. Wilson" and "Evolution." It is a most robust growing sort, and on that account should be sown thinly. The pods are large and handsome, terminating in an abrupt hook, and contain from seven to ten very large deep green peas of excellent quality. It is undoubtedly one of the heaviest late croppers in existence. Awarded full marks of merit by the Royal Horticultural Society. **In sealed Half-pint Packets, 2/6 each.**

NEW CULINARY PEA, THE GLADSTONE.

In Half-pint Packets, 2/- each.

MELON, DIAMOND JUBILEE.

First Class Certificate, Scottish Hortcultural Society, August 3rd, 1897.

This variety is the result of a cross between "Best of All" and "Countess," and is a decided improvement on both these well-known kinds. The fruits are oblong in shape, beautifully netted and assume a pretty golden-yellow when ripe; weight from 3 to 5 lb., flesh greenish-white, flavour excellent, a distinct acquisition for early crops, and will prove a boon to market growers. **Per Packet, 1/6.**

Wholesale only from HURST & SON, 152, HOUNDSDITCH, LONDON, E.

SANKEYS' famous GARDEN POTS

✻ Bulwell Potteries, Nottingham. ✻

Messrs. Dicksons, Limited, Chester, write; "The Flower Pots you have so largely supplied us with are light strong, and well made, and in every respect highly satisfactory."

Messrs. Richard Smith & Co., Worcester, write: "We beg to say that we are highly satisfied with your 'Garden Pot.' They are well made, light, yet strong, and we like them better than any other we have ever used."

Messrs. Fisher, Son, and Sibray, Limited, Handsworth Nurseries, Sheffield, write: "We have pleasure in testifying that after having used your pots for the past twenty-five years, we have found them all that could be desired."

GREENHOUSES from £3 8s. VINERIES, conservatories, well-made frames, painted or glazed, from 21s.; illustrated price lists free. Maker to H.M. the Queen and H.R.H. the Prince of Wales.

POTTER, HAWTHORN, and CO.,

(Name Paper.)

NEW TWINE NETTING, 2 yds. wide, 3d. per yd.; 4 yds. wide, 6d. per yd. 1 inch mesh Tanned Netting, 2 yds. wide, 1d. per yd., 8s. 100 yds.; 4 yds. wide, 16s. per 100 yds. Suitable for seed-beds and lawn tennis courts. All kinds of nets made to order. Established 50 years.—W. CULLINGFORD, 177, Markhouse Road, Walthamstow.

1898 FORBES' CATALOGUE 1898

(over 150 pages—nearly 150 illustrations) of

FLORIST'S FLOWERS and HARDY BORDER PLANTS

is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.

It gives full and ACCURATE DESCRIPTIONS of everything in the way of FLORIST'S FLOWERS, also COLOUR, HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.

It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

SHEPPERSON'S NOVELTIES & SPECIALITIES.

THIRTY-NINTH YEAR OF ADVERTISING.

The following NOVELTIES and SPECIALITIES having all been grown in a very exposed situation high up on the Derbyshire hills are very hardy, stocky, and healthy, very different to weak seedlings grown in warm favoured situations, which look nice, but very rarely succeed well. All Carriage Free for Cash with order. Descriptive List free.

CHRYSANTHEMUMS (Special Culture), not a collection of old-fashioned sorts, but the cream only of the best English, French, American, and Japanese raisers. Good, well-rooted plants, 12 for 2s., 25 for 3s. 6d., true to name

CARNATIONS, PICOTEES, and CLOVES of the finest-named hardy border varieties, many grand new sorts, strong layers wintered outside, 6 for 2s. 6d., 12 for 4s., 25 (in twelve varieties) for 7s. 6d , unnamed varieties 3s. per doz.

NEW HARDY JAPANESE PRIMULAS.—This class of hardy Primula, which has become so popular either for the outside border or the greenhouse since its introduction, has been greatly improved Six distinct varieties (named) for 2s. 6d.; 12 for 4s.; 25 in 12 varieties for 7s 6d.

CARNATIONS, PICOTEES, and CLOVES.—Will produce 80 per cent. of fine double flowers, in self, striped, and spotted varieties, including whites and yellows, all from the finest strains for the borders, 12 for 2s. 6d., 25 for 4s. 6d., 50 for 8s.

PRIMULA CASHMERANA.—A really fine spring-flowering plant. Colour, bright mauvy violet. Free bloomer Should be in every garden. Three for 1s. 6d., 6 for 2s. 6d., 12 for 4s.

PHLOXES (Perennials).—Special culture of early and late varieties, the cream only from Downie, Laird and Sons, Kelway, Ware, and other first growers. Six fine varieties for 2s., 12 for 3s., 25 for 5s. 6d., true to name. Strong stools to bloom well.

VIOLAS, during the past few years, have come to the front as few flowers have ever done. They are wanted everywhere, and very few plants produce so fine a display for so little trouble. I have a grand collection, including many new varieties, 12 varieties, 1s. 6d.; 25 for 2s. 6d.; 50, in 25 varieties, for 4s. 6d.; true to name.

PYRETHRUMS (Double and Single).—A grand collection to name, selected from the best English and French raisers as a hardy, free-flowering, easily-grown plant for all purposes. 3 named varieties, 1s. 6d. ; 6 for 2s. 6d. ; 12 for 4s. ; unnamed varieties, 3s. per dozen.

GAILLARDIAS (Perennial Hybrids). — A really grand collection of these most gorgeously marked hardy plants. Colours—Scarlet, crimson, and gold, of different shades; blooms all summer; good strong plants, 6 for 1s. 6d. ; 12 for 2s. 6d. ; 25 for 4s. 6d.

HOLLYHOCKS. — Warranted all fine double flowers; Chater's and Ware's select strain, strong year-old plants to bloom this summer. 6 varieties, 2s.; 12 for 3s.; 25 for 5s. 6d.

ASTERS (Michaelmas Daisies).—Unrivalled hardy autumn-flowering border plants, for cut flowers, &c. A grand collection of the latest improved colours. Six distinct sorts, 1s. 6d. ; 12 for 2s. 6d. ; 25, in 12 varieties, 4s. 6d.

CANTERBURY BELLS. — Grand new colours and new forms, double and single, Hose in Hose, Cup and Saucer, and other varieties, 12 plants to bloom well, 1s. 6d. ; 25 for 2s. 6d.

GERANIUMS. — Greenhouse varieties. Double and single, by Pearson, and other first-class raisers. Good, well-rooted plants, out of pots, 3s. per dozen; true to name.

DELPHINIUMS. — A splendid lot, raised from 12 varieties of Kelway's. Double and Single, including all shades of Blue, from the very palest to the darkest. Good plants to bloom well, 6 for 2s. ; 12 for 3s. ; 25 for 5s. 6d.

IRIS GERMANICA.—Rivals of the famed orchid, flowers of peculiar formation, and most exquisitely marked with many bright and distinct colours. Quite hardy. 3 named varieties, 1s. 6d. ; 6 for 2s. 6d. ; 12 for 4s. ; 25, in 12 varieties. for 7s. 6d.

GEUMS.—The new Double Scarlet. A splendid hardy, free blooming plant, fine for cutting, 12 for 1s. 6d. ; 25 for 2s. 6d. ; 50 for 4s. 6d.

AQUILEGIAS.—A grand collection, including many new colours and new forms; 12 best mixed varieties for 2s.

PENTSTEMONS.—A splendid collection to name; a very showy and useful bedding plant, 3s. per dozen ; 25 for 5s, 6d.

PINK (Fimbriata alba major).—Large white fimbriated flowers. A very free bloomer. Should be in every garden. Good plants 2s. per doz. ; 6 for 1s. 3d.

CAMPANULA PERSICIFOLIA. — Single White, Double White, Single Blue, and Double Blue. All quite hardy, and unrivalled for border decoration, cut flowers, wreaths, &c. 1 of each for 1s. 6d. ; 2 of each for 2s. 6d.

DORONICUMS (Golden Stars or hardy Marguerites).—Three first-class sorts. Harper Crewe, Clusii, and Plantagineum excelsum. 1 of each for 1s. 6d. ; 2 of each for 2s. 6d.

TOMATO PLANTS.—Two first-class varieties, Challenger and Conference; good plants, 1s. 6d. per doz. Ready in April ; order at once.

12 BEAUTIFULLY Spotted or pure White FOXGLOVES for 1s. 6d.; 25 for 2s. 6d.

POLYANTHUS and PRIMROSE (Hybrids).—Splendid mixed colours; finest strain grown. 12 for 1s. 6d. ; 25 for 2s. 6d. ; 50 for 4s. 6d.

ARMERIA (Thrift). — Pink and white flowers. Plant dwarf and cushion-like. Very useful for rockeries and edging to borders. Quite hardy. 2s. per dozen ; 25 for 3s. 6d.

LYCHNIS DIOICA RUBRA.—Double crimson flowers. A useful, neat plant. This has been greatly admired by all who have seen it ; three for 1s. 6d. ; six for 2s. 6d.

12 HARDY Perennial BORDER PLANTS, named, distinct, and useful for decoration and cutting purposes, 2s.

POTENTILLAS.—A distinct and interesting class of hardy border or rock plants, producing an abundance of flowers of a splendid velvety texture, which are very attractive and ornamental, and for cut flowers they are grand. Three for 1s. 6d., 6 for 2s. 6d., 12 for 4s., true to name.

FUCHSIAS, for Exhibition or Decoration. Order at once for delivery in April. I have a very fine collection, including many new varieties, double and single, light and dark, good healthy plants. 2s. per dozen, true to name.

A MAMMOTH SWEET WILLIAM (Holborn Glory).—This is, without doubt, the largest-flowered Sweet William ever sent out, the florets being much larger than penny pieces. An unequalled speciality for collections of biennials, border, or herbaceous plants. Unaproached for show, exhibition, or staging purposes. 12 for 1s. 6d., 25 for 2s. 6d., good strong plants.

CARNATION.—Margaret. This grand novelty has proved itself to be the most remarkable of all the carnation family. It commences to bloom early in summer and go on till late autumn. It will produce quite 80 per cent. of fine double flowers of a great variety of the most beautiful colours and markings. 12 plants for 2s., 25 for 3s. 6d.

SEEDLING PANSIES (Fancy). — Strong plants to bloom well. 1s. 6d. per dozen, 50 for 5s. 6d.

STRAWBERRY PLANTS.—British Queen, Brown's Wonder, Duke of Edinburgh, President, Sir Joseph Paxton, Sensation, and many other good sorts, strong fruiting crowns. 3s. per 100.

WALLFLOWERS.—Ware's Dwarf Blood-Red and Yellow, also Primrose Dame, good strong plants, all transplanted. 1s. per doz., 6s. per 100.

NO LADDERS—NO CLIMBING—NO ACCIDENTS—BETTER RESULTS.

Gentlemen, and even Ladies will find it provides an interesting and fascinating pastime without much outlay.
Highest Awards by the Royal Horticultural Society. Used in the Gardens of Her Majesty the Queen, H.R.H. the Prince of Wales, the Seats of the Nobility and Gentry, the National Parks, and the largest Nurseries.

Pruning in the year 1898.

THE "STANDARD" TREE PRUNER.
Lengths from 2 feet to 14 feet. Prices from **4s. 6d.** to **13s.**
The "Standard" Tree Pruner is known throughout the world as one of the most useful inventions for assisting the growth and increasing the fruit-bearing properties of trees.

THE "MYTICUTTAH."
For Pruning Dwarf Trees, Shrubs, Bushes, Roots, &c.
Large size, **9s. 6d.**; Small size, **8s. 6d.**

THE "GIANT."
The most powerful pruning implement in the world.
Lengths from 4 feet to 14 feet.
Prices from **22s.** to **32s.** each.

THE "FULCRA."
Cutting capacity midway between "Standard" and "Giant."
Lengths from 6 feet to 14 feet.
Prices from **14s. 6d.** to **22s.** each.

The "Ærial" Pruning Saws, Switches, and Hooks, Fruit, Flower, and Grape Gatherers; Weed Destroyers, Leaf Lifters, &c.

Pruning in the Olden Time.

Sold by Nurserymen, Seedsmen, Ironmongers, the leading Stores, &c., of whom Price Lists can be had, or of—
THE STANDARD MANUFACTURING COMPANY, St. Alkmund's Churchyard, DERBY.
Horticultural Implement Makers and Purveyors by Royal Warrant to Her Majesty the Queen.

SAVE HALF THE COST.
GARSIDE'S BEDFORDSHIRE SILVER SAND
(COARSE OR FINE) is admitted by the leading Nurserymen to be **THE BEST QUALITY** obtainable in the trade. Consumers should **BUY DIRECT** from the owner of these celebrated and extensive Pits, which contain a practically inexhaustible supply of splendid Sand, and thus *save half the ordinary cost.* APPLY DIRECT TO THE PROPRIETOR FOR SAMPLES AND PRICES free on rail or canal. All orders executed with the utmost promptness and under personal supervision. Special railway rates in force to all parts. All kinds of PEAT supplied at lowest possible prices. Sample bag sent on application.
GEORGE GARSIDE, Jun., F.R.H.S., LEIGHTON BUZZARD, BEDS.

The Stourbridge Heating Apparatus,
For Greenhouses, Conservatories, &c.
Most economical and efficient. This apparatus has attained great popularity. Made at our own foundry, and under our own supervision. Before ordering elsewhere, send for Price List, giving full particulars, free by post.
J. and W. WOOD,
Birmingham Street Foundry,
STOURBRIDGE.

GARDEN PEAS—JUNE TO NOVEMBER.

We now offer the following, as representing the best collection selected from 1,024 rows we had under trial last season. It would be difficult for us to give precise dates for putting the seed into the ground, as so much depends upon soil and situation. Successional Sowings may be made any time between these dates, and the last sowing not later than the second week in June

NAME.	DESCRIPTION.	HEIGHT. ft.	WHEN TO SOW.	EXPECT READY TO PICK.	CARRIAGE FREE. Per Pint.	Per Qrt.
Carters' Lightning	First Early White Round	2½	In February	May to June	2s.	3s. 6d.
Carters' Early Morn	First Early Marrowfat	3	End of March	During June	2s.	3s. 6d.
Carters' Daisy	Second Early Marrowfat	1½	Middle of April	Early July	2s.	3s. 6d.
Carters' Danby Stratagem	Mid-season Marrowfat	3	End of April	July	2s.	3s. 6d.
Carters' Model Telephone	Main Crop Marrowfat	5	Middle of April	July	2s.	3s. 6d.
Carters' Model Telegraph	Main Crop Marrowfat	5	End of April	July and August	2s.	3s. 6d.
Carters' Michaelmas	Late Marrowfat	3	May to June	Sept. to Nov.	2s.	3s. 6d.

The Collection { **1 pint each of 7 varieties, price 12s. 6d.** }
{ **1 quart each of 7 varieties, price 22s. 6d.** } **Offered in Sealed Packets only. Carriage Free.**

AN EXHIBITION GARDEN FOR A FEW SHILLINGS.

CARTERS TESTED SEEDS CARTERS

Messrs. CARTER now offer the following liberal collection of their choicest Seeds for growing on for Exhibition purposes, or for comparison with the products of friends or neighbours who may not grow Exhibition Vegetables.

CARTERS' "HALF-GUINEA" BOX OF VEGETABLE SEEDS.

For Exhibition purposes, sent post free for **10/-** cash. It contains One Packet each of the following grand assortment:—

- PEAS—
  - CARTERS' DAISY.
  - CARTERS' MODEL TELEPHONE.
  - CARTERS' DANBY STRATAGEM.
  - CARTERS' MODEL TELEGRAPH.
- BEANS—
  - CARTERS' LEVIATHAN.
  - CARTERS' CANADIAN WONDER.
  - CARTERS' ELEPHANT RUNNER.
- BEET—
  - CARTERS' PERFECTION.
  - CARTERS' CRIMSON BALL.
- BORECOLE—
  - CARTERS' WELSH.
- BRUSSELS SPROUTS—
  - CARTERS' HOLBORN EXHIBITION.
- CABBAGE—
  - CARTERS' HEARTWELL.
  - CARTERS' BEEFHEART.
- SAVOY—
  - CARTERS' GREEN CURLED.
- CAULIFLOWER—
  - CARTERS' DEFIANCE.
  - CARTERS' EARLY AUTUMN GIANT.
- CARROT—
  - CARTERS' SUMMER FAVOURITE.
  - CARTERS' SCARLET PERFECTION.
- CELERY—
  - CARTERS' INCOMPARABLE CRIMSON.
  - CARTERS' SOLID IVORY.
- CUCUMBER—
  - CARTERS' MODEL.
- LEEK—
  - CARTERS' HOLBORN MODEL.
- PARSNIP—
  - CARTERS' MALTESE.
- LETTUCE—
  - CARTERS' GIANT WHITE COS.
  - CARTERS' HARBINGER.
- ONION—
  - CARTERS' RECORD.
  - CARTERS' TENNIS BALL.
- TOMATO—
  - CARTERS' PERFECTION.
- TURNIP—
  - CARTERS' JERSEY LILY.
- VEGETABLE MARROW—
  - CARTERS' VEGETABLE CREAM.

Full particulars of other Boxes of Seeds, containing one year's supply, from 2/6 to 84/ sent Post Free.

THE QUEEN'S SEEDSMEN. Carters HIGH HOLBORN, LONDON.

VEITCHS' FLOWER SEEDS

AQUILEGIAS,
VEITCHS' HYBRID.

These comprise many new and beautiful shades and combinations. Very effective.

Per Packet, 1s. 6d.

BEGONIA,
Veitchs' Choicest Hybrid.

Saved from the very finest and newest hybrids, and is undoubtedly the best strain yet offered.

Per Packet, 1s. 6d.

CAMPANULA PYRAMIDALIS COMPACTA,
WHITE (NEW).

SYON HOUSE VARIETY.

Award of Merit, R.H.S., July 18, 1896.

A beautiful white form of this most useful decorative plant.

Per Packet, 1s.

CARNATION,
Veitchs' Early-Flowering Perpetual.

An improved strain of the Marguerite section, combining the earliness and free-flowering habit of that class with the quality and substance of the Tree Carnation.

Per Packet, 2s. 6d.

Veitchs' Gigantic White Primula,

A magnificent free-flowering Fern leaved variety of strong growth, remarkable for the enormous size, great substance, and elegant form of its flowers, which are pure white and relieved by a well formed citron-yellow eye. This is the largest flowered Primula known. **Per Packet, 2s. 6d.**

CYCLAMEN,
VEITCHS' CHOICE,

J. VEITCH & SONS, LTD., were awarded a Special Certificate by the Royal Horticultural Society for superior quality.

Per Packet, 2s. 6d.

GLOXINIA,
VEITCHS' SUPERB MIXED

This strain of Gloxinia is of the most profuse-flowering character, with the greatest diversity in the colours, ; flowers large and open, growth vigorous. Saved from our newest and best sorts.

Per Packet, 2s 6d.

HIBISCUS MANIHOT.
Award of Merit, R.H.S., Sept. 7, 1897.

This strikingly beautiful decorative plant attains a height of about 4 feet, producing flowers fully 4 inches in diameter, their colour being a soft clear sulphur-yellow, with a conspicuous maroon blotch at the base of each petal.

Per Packet, 2s. 6d.

STREPTOCARPUS.
VEITCHS' WHITE.

A striking and valuable large-flowering variety of our well-known improved strain. A most desirable acquisition.

Per Packet, 2s. 6d.

For full description of the above and many Choice NOVELTIES and SPECIALITIES, CATALOGUE, forwarded gratis and post application.

JAMES VEITCH AND SONS, LTD., ROYAL EXOTIC NURSERY, CHELSEA, S.W.

THE GARDENERS' MAGAZINE.

SATURDAY, MARCH 5, 1898.

ASCOT, SUNNINGHILL, SUNNINGDALE, AND DISTRICT HORTICULTURAL SOCIETY.

CHRYSANTHEMUM SHOW, NOVEMBER 16 and 17.

Open Prizes—

Class 1. Best 24 Japanese Blooms, distinct varieties, 1st, £6; 2nd, £4; 3rd, £2; 4th, £1.

Class 2. Best 24 Incurved Blooms, distinct varieties, 1st, £4 10s.; 2nd, £3; 3rd, £1 10s.; 4th, 15s.

Class 3. For the Best Group of Chrysanthemums, mixed with Foliage Plants and Ferns, to occupy a circular space not exceeding 8 feet diameter; quality and general effect to be the leading features (presented by Miss J. Durning Smith), 1st, £4; 2nd, £3; 3rd, £2.

HARROGATE HORSE AND HORTICULTURAL SOCIETY. This popular FLOWER SHOW is fixed for AUGUST 18 and 19 Over £150 in prizes.

L. HOBKINSON, Secretary.

SHREWSBURY GREAT FLORAL FETE,

AUGUST 17 and 18, 1898.

The Prizes in the Schedule amount to £950, with Gold and Silver Medals, &c.

Schedules post free on application to the Hon. Secs.,

Messrs ADNITT. and NAUNTON, The Square, Shrewsbury.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at One Shilling per line, the minimum charge being Five Shillings. Advertisement Office, 148 and 149, Aldersgate Street, London, E.C.

A COLOURED PLATE of

DENDROBIUM SCHRODERIANUM

Is presented with this Number.

Subscribers should see that their Newsagents deliver the Coloured Plate with each copy.

NOTES OF THE WEEK.

LIGHT.

NOW that the lengthening days have reached the point of equality with the shortening nights, and all vegetation is responding to the increasing bounty of the sun by bursting of buds into leaf, and even into blossom, we may not unprofitably devote a little consideration to the wonderful nature of this light, which practically does all the work. If we take a sunbeam and dissect it, as we may do by simply passing it through a triangular piece of cut glass, we find it to consist of a graduated series of coloured rays visible to the eye and others which are invisible, and constitute the heat rays. In the rainbow we see this dissection effected by the raindrops, and by both these examples we learn that the apparently simple beam of light is really of a very complex nature indeed, while the scientist who deals with it spectroscopically will tell us that besides this mixed and varied nature the little rainbow he artificially produces is crossed with innumerable dark lines, each of which is characteristic of some elemental substance present in the source of the light, forming, in fact, a clearly written catalogue of the solar materials. So much for the constitution of the light, which is hardly more wonderful than its effects upon our floral and other vegetation. Under its genial stimulus the little green cells, by means of the sympathetic action of the chlorophyll granules they contain, are all busy in a myriad various ways splitting up and fashioning themselves into solid woody tissues, with all their varieties of bark, pith, and sap circulatory apparatus; roots, massive or delicate, burrowing away underground to find the needful water and earthy materials for the work going on above; the buds of leaf or bloom are swelling beneath the influence of the supply from below; the warmth from above and the busy multiplication of the cells within. Lo! suddenly the brown or black bud splits open, and out come the delicate green embryos of the future foliage to greet the vivifying sunbeam and profit still more by its genial influence. Everywhere in the garden and in the grove this wondrous work is going on above and below the ground, and with ever greater activity as the daily reign of the sunbeam increases. But this is not all. Every blossom has its own special liking for this or that coloured part of the dissected ray, and absorbing that and rejecting the others, greets one's eyes with the tints it rejects. Yon flaunting group of golden crocus has sucked into itself, all the hues but the reflected ones; the scarlet tulip chooses differently but precisely here in this tulip tribe, comes in the curious fact that a seedling may for year after year be true to its first love, as it were, and then a "break" occurs and ever afterwards its annual chalice will flame on other lines altogether. The stately lily, white as the driven snow, rejects and reflects all the intrusive beams save where the crimson pollen and the delicate greenish stigma make contrasting choice to increase the lady's charms. It is of course a moot point as regards the stimulating effect of the sunbeam, how much is actually due to the visible or coloured rays, and how much to those invisible ones into which the dark violet beams merge, and which carry with them that potent factor of warmth. These may be gathered up by a lens or burning glass precisely as the light rays can be, and yet though no bright spot is visible at the focus, the heat is none the less intense. Doubtless, these do a large part of the work, but the combination of both is essential to proper vegetative action.

POTATOS ON LIGHT SOILS.

DURING 1897 two series of experiments in potato culture were carried out at Calne under the auspices of the Wilts County Council, with a view to determine the most profitable varieties and the most suitable manures for heavy and light soils. At the Quemerford station the soil was somewhat heavy, and, as shown in the summary of the trials, in our issue of the 19th ult., the best results were in the large group of plots obtained by the use of complete chemical manure which consisted of equal parts (by weight) of superphosphate, kainit, and nitrate of soda. The other station is known as Lickhill, and the results obtained are of considerable value as illustrating the importance of taking into consideration the peculiarities of the soil and climate in determining the course of procedure to be adopted. At Lickhill, where the soil is light, and contains a large percentage of lime, three of the plots devoted to potatos were not manured, and in these the average yield was five tons fifteen hundredweight and twenty-two pounds per acre. Stable manure was applied to three plots, at the rate of sixteen tons per acre, and these plots gave an average crop at the rate of nine tons seventeen hundredweight per acre. The increase from the use of stable manure, therefore, amounted to four tons one hundredweight per acre, or a gain in value of £5 10s., after deducting £4 for cost of manure. The remaining plots were treated with complete chemical manure, the mineral superphosphate and kainit being applied at the time of planting. To minimise the loss by drainage, the nitrate of soda was applied in dressings at the rate of one pound per perch, three dressings being given to the heavily-manured plots, and two to those receiving the medium quantity of manure. Two plots received dressings of nine pounds, three six pounds, and one three pounds per perch, and in the first case the increased yield represented a gain of £3 7s., in the second of £3 8s., and the third £2 1s. per acre, and these figures show that the medium dressing gave the most satisfactory results, and that the most profitable crop was obtained with stable manure. The growth of the plants on the plots to which the stable manure was applied suffered less from the drought experienced early in the summer, whilst, on the other hand, the growth was most rapid after rain on the plots to which chemical manure had been applied. It is apparent from these facts that the best course is to use stable manure, supplemented by artificials, in accordance with the advice so consistently given in these pages. Six varieties were grown at the Lickhill station, two of which—Reading Giant and Stourbridge Glory—are largely cultivated in the Calne district. The other varieties included in the experiments were Daniel's Dreadnought and Imperator, two late varieties, and Early Puritan and Reading Russet, which belongs to the mid-season. The early varieties differed but little in productiveness, but Puritan was of the finest quality when cooked. The average yield per acre of the late varieties was: Imperator, ten tons eleven hundredweight, twenty-two pounds; Reading Giant, eight tons thirteen hundredweight twenty-two pounds; Daniel's Dreadnought, eight tons two hundredweight sixty-seven pounds; Stourbridge Glory, seven tons eleven hundredweight twenty-two pounds. The four varieties proved equally susceptible to the influence of fertilisers, and yielded about the same weight per acre of diseased tubers, the slight difference shown being in favour of Reading Giant and Stourbridge Glory. They all gave a heavier crop as the result of spraying, this increase being well marked in the case of Daniel's Dreadnought and Imperator.

THE PLEASANT SPRINGTIME.

THE snowdrop and crocus, chionodoxa and early scillas are already passing out of bloom in our London parks, and especially in those cosy nooks and corners where they are planted in the turf, and send up their blossoms above the verdant grass. In the Regent's Park especially, but also in other London parks, the planting of spring bulbs in the turf is somewhat extensively carried out, and charming effects are produced, to the great delight of those who frequent the parks. Some years ago the planting of spring-flowering bulbs in grass lawns was much followed, but the application of the scythe or mowing machine when their foliage was in full vigour of development soon caused the death of the bulbs. At one time the green banks which form the base of the historic round tower of Windsor Castle, was gay at this season of the year with pretty designs in snowdrops, but they all have disappeared, sacrificed, doubtless, to the scythe. In our London parks all these patches are carefully guarded, and until the foliage has faded, and their work accomplished, these precious spots are held to be sacred, and any necessary roughness of appearance for a time is amply compensated for by the floral service rendered earlier in the year. It may not be known to many that in the leading parks there are reserve gardens or nurseries, in which the bulbs that are to be effective in spring are propagated in an extensive manner. In the Regent's Park, for instance, there is a large enclosed garden in which thousands of bulbs are annually grown for the necessary supply. Hyacinths, tulips, narcissi, and others are carefully lifted when the time to replant the beds with summer-flowering subjects comes round; they are carefully taken to a room fitted up in the way of an ordinary fruit-room, but with movable trays forming the shelves, and in these trays the bulbs are carefully placed and covered with a layer of finely-sifted cinder ashes; here they remain until the end of the summer with but little loss of vigour, being kept in semi-darkness and cool. During the late summer months advantage is taken of leisure moments to go over the bulbs; select and sort them. Those which are strong enough to flower are replanted in the parks, the offsets are planted in beds in the reserve garden and grown on into size. This garden supplies practical illustration of the management of bulbs of an extremely interesting character, and as far as hyacinths and tulips are concerned three years generally, but two in some cases, suffice them to reach a blooming size and when it is considered that four thousand bulbs of tulips are required to fill one of the largest raised circular beds, some idea of the number required may be thus arrived at. The care with which the reserve garden is managed is seen in the fact that it is rarely a flower of another variety is found in a bed comprising one sort only, and generally it is due to the sportiveness or the breaking into some other form peculiar to the tulip. Unlike those of hyacinth and the daffodil, the bulb of the tulip dies every year, but produces others that perpetuate faithfully the parent variety. At taking-up time, the old bulb is found as merely a few loose skins wrapped round the new, and of the new progeny there may be two strong enough to flower with a few small offsets, which require time to grow to a flowering size, and in the reserve garden they are led on until large enough to produce an inflorescence.

San Jose Scale.—While in this country the possible introduction of this destructive pest into the orchards and gardens of the United Kingdom is regarded with supreme indifference, a considerable amount of activity is being evinced elsewhere with a view to prevent infestation. The German Minister of Agriculture is taking active measures with regard to the possible infestation of fruit trees in Germany by the San José scale. A small committee of entomologists and horticulturists has been appointed to investigate the matter, and steps are being taken to render fruit-growers and other cultivators familiar with the appearance and the life-history of the pest. In Ontario also fruit-growers are endeavouring to prevent the importation of fresh fruits and nursery stock from the United States, on account of the risk of introducing the destructive scale into the fertile Canadian fruit region between the lakes. Within the past few days the New Jersey experiment station has issued a bulletin, in which it is stated that all hope of exterminating the insect in that Atlantic State must now be abandoned. It is already well established there in gardens and orchards—hedges, small fruits, and tree fruits all being infested. From badly-infested orchards the pest is spreading through the agency of birds. Peaches are especially sensitive to attack, and perish in three or four years from the first appearance of the scale if the latter is allowed to pursue its course unchecked. Thin-leafed varieties of plums appear to come next, then pears, and finally apples. On the other hand, some varieties of cherries seem to be almost exempt. The boundless reproductive powers of the insect and its inconspicuous nature render it especially dangerous, and the opinion is expressed that the San José or pernicious scale is the worst and most destructive insect pest that has ever appeared in New Jersey. Unchecked, it will in time ruin any tree it attacks, and will render the fruit unmarketable long before the tree itself dies. In Ohio it has been found that, besides apples, plums, peaches, gooseberries, currants, raspberries, and roses, the San José scale attacks the grape vine, the lime tree, the elm, the walnut, the Lombardy poplar, the sweet chestnut, and the guelder rose. The several species of the cotoneaster are also specially liable to attack from this scale. In the State of Virginia, where the scale first appeared in 1893, it has not, through lack of systematic treatment, been thoroughly subjugated, and further trouble is anticipated. In Kentucky there is a demand for legislation against the spread of the scale. A fact, about which more is becoming known and should receive considerable attention in the future development of economic entomology, is that insecticides appear to have different effects in different regions. Thus, it is asserted that insects which succumb readily to kerosine in the Atlantic States defy it absolutely in Colorado. Again, washes that easily destroy the San José scale in California are ineffective in the Atlantic States, where this insect appears to be materially altering its habits and peculiarities.

A History of the London Parks has been written by Lieut.-Colonel J. J. Sexby, chief officer of the London County Council Parks Department, and will be published, we are informed, by Mr. Elliot Stock in May. Colonel Sexby has devoted a great deal of attention to the preparation of this work, in which he will describe not only the leading features of the County Council's parks, but will also recount their history and associations. He has been engaged on this important work for several years, and has collected all local and other information which can possibly be obtained on the subject. No one is better qualified to write a history of London parks, as during the period that Colonel Sexby has been the head of the Parks Department of the County Council the area of the parks has been increased by over 1,000 acres, and the special facilities for increasing recreation and public enjoyment introduced, which have made the London parks known throughout the world.

Cool Treatment of Cœlogyne cristata.—Mr. W. H. Atki[illegible], the [illegible] trar of the Batley Cemetery, sends us a photograph of a group of [illegible] examples of the Chatsworth variety of Cœlogyne cristata, to show h[illegible] this beautiful form succeeds under cool treatment. With the photograph Mr. Atkinson sends us the following particulars: In your issue of February [illegible] "Work for the Week," Mr. Stafford gave some notes on Cœlogyne cristata [illegible] "warm orchids." I have always held that this is best grown as a cool [illegible] and herewith I send a print from a photograph taken by myself on W[illegible] from my plants of the Chatsworth variety of C. cristata. I bought the original [illegible] years ago, and at once placed it in a house among a few odontoglossums I [illegible] and in which I also grow bedding plants and a general assortment of other things. In this structure the winter temperature averages about 53 degrees by day, and [illegible] degrees by night (sometimes lower). The plant has never failed to bloom, and has filled a ten-inch pan, and has also given me the plants occupying a five-inch [illegible] and a five-and-a-half inch pot, which stand in front of it. I sometimes [illegible] or two in cold, foggy weather, but not often. The appearance of the plant [illegible] demonstrates that cool treatment agrees with this beautiful orchid.

Advice to Young Gardeners.—Mr. M. Todd, the genial president of the Scottish Horticultural Association, has been giving some good advice to young gardeners. Mr. Todd pointed out that the young gardeners have the future before them and it is they who must specially be looked to, to carry on the work of the garden. At the present day every facility is offered to young men to enable them to reach a height of attainment quite impossible to the generation now getting old. "See to it, then, young men," he said, "that you let not your opportunities pass by unheeded. 'There is a tide in the affairs of men which, taken at the flood leads on to fortune.' That tide may pass when you are idling by. Lose no chance of thoroughly equipping yourselves in every department of your profession. Above all things, make yourselves cultured men as well as competent gardeners, men of high character as well as of high attainments; men of wide ge[illegible] knowledge and intelligence; masters, if you can, of some one branch of gardening, but with a wide knowledge of all departments. To know everything about something is a very excellent thing, but to know a good deal about everything is still better. Specialists are eminently valuable, but even more so are all-round [illegible] Be thoroughly qualified for the best situations and the chances are they will come your way. Remember, too, that your membership of this association brings a responsibility. Its final success will be judged by what manner of men you p[illegible] yourselves to be. By your works ye shall be judged, and the association [illegible] have laboured in vain if the coming generation of gardeners be no improvement on the past. Your country as well as this association calls you to a high ideal of your duty. Scotland has long been famed for the excellence and intelligence of its gardeners. In every country where civilization has spread, there have Scotsmen been to the front as cultivators of the soil; and traitors to your country of the worst description will ye be, if in your hands its fair fame be tarnished."

The Economic Resources of the West Indies form at present [illegible] a large item of general interest that nothing could be more appropriate than the publication of a general survey drawn up by Dr. Morris, C.M.G., Assistant D[illegible] of the Royal Gardens, Kew, for the use of the Royal Commission of Inquiry, [illegible] which he was attached as expert adviser in botanical and agricultural [illegible] The publication is issued as the first of an additional series of the *Kew* [illegible] its price is 1s. 6d.; it is bound in stiff boards, contains a good map of our [illegible] Indian Colonies and one hundred and sixty-five pages of matter that is of [illegible] to all, and of great value to colonists. We thoroughly endorse the opinion [illegible] pressed in the preface that Dr. Morris's residence in the West Indies, his re[illegible] visits to them, and his intimate knowledge of their conditions have enabled him to produce an account as accurate as it is impartial of their natural and economic resources, which is certainly more complete than anything hitherto available. Why the West Indian Colonies have failed to reach success, and in what direction the path to it lies in the future, can be readily understood by anyone who will take the trouble to read the handy little volume.

Scottish Horticultural Association.—The Transactions of this [illegible] cessful society for the past year has been recently issued, and, as usual, [illegible] publication contains much to interest those engaged in the several branches [illegible] horticulture. Abstracts of the several papers that were read at the monthly meetings during the year are given, with the full text of the presidential address delivered by Mr. M. Todd at the annual meeting in February last. The Transactions include, as a matter of course, the report and balance-sheet for the [illegible] year, and these, as stated in our report of the annual meeting, are eminen[illegible] factory. The arrangements for the monthly meetings are as follows: [illegible] The Supply of Vegetables to the Edinburgh and Glasgow Markets, Mr. [illegible] Scarlett; May 3, Bulb-growing in Lincolnshire, Mr. J. Alexander; June 7, The Cultivation of the Fuchsia for Exhibition, Mr. A. Johnstone; July 5, Cr[illegible] Mr. J. M'Intyre; August 2, The Cultivation of the Most Useful Orchids for C[illegible] Flowers, Mr. Wm. Boyd; September 6, The History and Development of the [illegible] Rose, with Hints on its Cultivation, Mr. T. Dale; October 4, The [illegible] of the Press on Horticulture, Mr. A. S. Galt; November [illegible] Chrysanthemum for Cut Bloom and Conservatory Decoration, [illegible] M'Donald; December 6, The Arrangement of Hardy Plants in the Garden, [illegible] A. Wright; and January 10, 1899, Annual General Meeting. A supper [illegible] occasion of the association attaining its majority will take place at the [illegible] Hotel, Edinburgh, on Wednesday, March 9, at seven o'clock.

The History of the Zonal Pelargonium formed the subject [illegible] interesting lecture given by Mr. H. Cannell, on Friday last, at Bickley. [illegible] lecturer dealt chiefly with the progress made in zonal pelargoniums [illegible] past fifty years, and illustrated his remarks with flowers of leading varieties [illegible] measuring nearly three inches across.

Two Famous Trees.—The precocious horse-chestnut tree in the Champs Elysees, Paris, will not bloom on March 20 this year, however often it may have flowered on that date previously, or it is now dead, much to the regret of Parisians. We understand that the huge rose tree at Hildesheim is in a bad way, for the decay that comes with old age is apparent, and is, in this case, assisted by a fungoid attack. Herr Waldheim, of the Hanover Botanic Gardens, has been devising means to save the life of this patriarchal rose, but it is questionable whether success will attend his efforts.

Royal Gardeners' Orphan Fund.—The first meeting of the committee of this charity for the current financial year, was held on February 25, when Mr. William Marshall was unanimously re-elected chairman of the committee. The guardians of the children elected at the annual general meeting were severally appointed, these being in most cases the mothers of the children. Authority was given to draw cheques in payment of their pensions from the date of election. Several special donations were reported by the secretary, among them being the following: Mr. M. Todd, Edinburgh, sale of flowers, £30 10s.; Mr. H. J. Jones, Lewisham, collecting box during the chrysanthemum season, £14 3s. 1d.; Mr. J. Gammie, £5 5s.; Mr. H. Eckford, Wem, sale of flowers, £2; and Mr. A. G. Weeks and Mr. Marks, 10s. each from boxes.

Old Herbals and Gardening Works are ever of more than passing interest even though many of them are not remarkable for their present day utility. Such books are now eagerly sought after, indeed the collecting of them has assumed the proportions of a miniature mania, and the leading dealers in old books are doing their best to meet the demand. On March 23 Messrs. Sotheby, Wilkinson, and Hodge will offer an extraordinary collection of herbals, chiefly printed before the years 1500. The first lot of all is an important and interesting French MS. of the fifteenth century, with the title "Le Livres des Simples Médecines," &c., with many hundred coloured drawings of plants, &c. There are one hundred and forty-nine lots of books relating to gardening, flowers, &c., and many are very rare. There is a fine copy of the beautiful volume dedicated to Marguerite de Valois, "Des Fleurs où sont contenuz plusieurs secretes de Médecine," 1581, and also a fine copy of Mollet's "Le Jardin de Plaisir," Stockholm, 1651, one of the rarest works on the subject.

The Kew Guild held its annual general meeting on February 24 under the presidency of Mr. G. Nicholson, A.L.S. Old Kewites were fairly well represented, and the lady gardeners were present. The report and balance-sheet were read and adopted, the latter showing the guild to have a substantial balance in hand in addition to the Thomson legacy now invested. In the report the committee recommended an alteration of Rule 2, allowing membership to all holding responsible positions in the establishment. This met with some opposition, as it was pointed out that stokers, carpenters, blacksmiths, gangers, &c., all held responsible positions, but the guild was not instituted to include them A hurriedly-drawn up amendment to the report, put with a view of altering the wording rather than the spirit of the committee's recommendation, was rejected because it failed to exclude the constables. Several interesting letters from old Kewites was read, and the committee and officers were re elected. Annual meetings generally consist largely of votes of thanks, but the Kew Guild has advanced ideas on this point, so only one vote was passed—and that unanimously to the chairman.

Epping Forest.—The committee responsible for the management of Epping Forest have presented their report for the past year to the Corporation of the City of London, and this shows that every part of this magnificent open space has received attention from the committee and Mr. McKenzie, the able superintendent. It is stated that a large area of the forest has been judiciously thinned in order to encourage the growth of young and promising trees—namely, oaks, beeches, and hollies—and with a view, also, of making the beauties of the domain more accessible. The portions thus dealt with include Theydon Coppice, St. Thomas's Quarters, Honey Lane Quarters, Loughton Forest, Whitehouse Plain, Lord's Bushes, and Walthamstow Forest. The committee also report that they have made an inspection of other portions of the forest where thinning is required, and instructions have been issued for the carrying out of the work during the present winter. In order to hide from view brick walls and other enclosures which do not improve the appearance of the forest in places, the planting of small clumps of trees has been carried on. Planting of a similar nature has been done on a portion of Wanstead Flats. At the desire of the inhabitants of the locality a portion of Bell Common has been planted with an avenue of trees in commemoration of her Majesty's Jubilee. The digging out of a large piece of swampy land known as Holloer Pond has been accomplished at a cost of £1,228, to which the Leyton District Council contributed £300 and the Corporation £650. The result is a fine sheet of water, some eight acres in extent. A suggestion by the Essex Field Club that the local museum in the forest should be enlarged has received due consideration from the committee, who report that the cost of the work is estimated at £250. The proposal will be further considered. The sale of thinnings during the year amounted to £643 13s. 9d. The keepers' wages were £1,150, and the labourers' wages £1,085. The committee recommend that £4,000 should be placed to the credit of the committee to meet the expenses of the coming year.

Royal Botanic Society.—At the meeting of this society on the 27th ult., Mr. Sowerby read the second part of his paper on "Fibres and the Plants Producing Them," dealing particularly with flax, hemp, and cotton. Several interesting exhibits were handed round, including a piece of mummy cloth made of flax, and supposed to be about three thousand years old. The following donations were reported: A fine specimen of the Rhododendron argenteum, presented by Mrs. Newall, of Gateshead-on-Tyne; and tubers of Nelumbium speciosum, &c., sent by Mr. W. G. Baker, curator of Oxford Botanic Gardens. At the meeting to be held on Saturday next there will be a microscopic exhibition of pollen grains.

MODERN RASPBERRY CULTURE.

FEW fruits in their season are more appreciated than raspberries, and given good culture few are more profitable. The plants, however, are too often starved by being allowed to occupy the same place for many years with little or no assistance in the shape of manure. But it is not always manure they need, but rather new soil, new site, and the removal of old worn-out stools. I have seen raspberry canes in gardens bearing as poor fruit as those produced in a wild state. Fortunately, of late years there has been a much greater interest taken in fruit culture, largely due to the spirited policy of the GARDENERS' MAGAZINE, and though raspberries have been referred to, there is still room for improved culture, and no need for great outlay. With more attention there will be better results, for a poor plant will take up as much room as a good one, and there is no question as to which pays the best. Few plants exhaust the soil sooner than the raspberry, owing to the rapid spread of its roots and the suckers it produces all round. Too often these strong canes are cut away, leaving the poor weak canes to bear the fruit. Overcrowding of canes is another source of weakness. Last summer I visited a garden where the owner told me his raspberries were a failure, and certainly they appeared as bad as could be, but here the plants had occupied the same position for at least a quarter of a century, and, of course, they and the soil were thoroughly worn out; the canes produced were like straws; the growth of healthy canes should be as thick as one's thumb.

With respect to raspberry culture, I have no new system to detail beyond remarking that raspberries should be grown for a much shorter time in the same place or soil than is generally the case. Our fruit trees occupy the land a long time, but we must deal differently with strawberries and raspberries, and a new plantation for the latter say every half-dozen years will give splendid results. The old system of planting under trees is objectionable, for though the plants will give a fair return if not too shaded we can now produce better late fruit by planting later varieties, and giving them a north border, and if possible, a moist soil for the latest crops. Many growers advise trenching before planting; indeed, I have seen this done to a depth of two to three feet, but so much depends upon the soil, and in our poor thin soil we only dig in a liberal quantity of manure, and then plant. If we trenched deeply we should place the good soil out of the reach of the roots, and add to the cost of labour. On the other hand, some soils would benefit by deep trenching, and the incorporation of any material that would enrich it. Position counts for a good deal, as a dry sloping bank is bad, and a wet place in some out-of-the-way corner is equally so. To do the plants justice, an open position, such as will grow other fruit well, is the best, and I fail to see why deep trenching is so often advised, for the raspberry is essentially surface-rooting. The soil most suitable is a holding loam, as it will produce the finest fruits, but not so early as a lighter soil on which by manuring I have grown good crops.

Planting is best done early in October, as then there is new root action before winter. If the room can be afforded avoid crowding in any way Many large market growers adopt an excellent plan, and allow a wide space between the rows of plants by putting rows of strawberries, &c., between. I advise at least six feet between the rows, two feet between the plants, and not more than three canes to a stool; grown thus there are better canes and finer fruit. There are other methods, such as planting against fences or as espaliers, but although this latter is advantageous in many respects, it does not produce the same weight of fruit as others. In the open, the three canes per stool should be strong enough to bear their own weight, and need but slight support when in a fruiting condition. Planting may be done as late as March with success, but the earlier date is best. The growth must be prepared in advance, so that it does not sink, and usually in October it is in a workable condition. Firm planting is essential, and the canes should be secured from vigorous stools, and not worn-out plantations; and to obtain them from as different a soil as possible. In soils that are poor, plant a vigorous grower like Superlative, and there will be better results. The medium growers do well in better soil, but even then avoid crowding, as this is fatal to success. The usual method after planting is to cut down the canes about half way, some cut less, but it should be borne in mind the first season's growth must be given to the plant to make roots and produce fruiting canes for another year, and there must be no fruit allowed the first season. We cut down to within six inches of the soil early in March, and only allow one or two at most of the suckers to furnish canes for next season. When the stools are at their best, never allow more than three canes, and these will give ample fruit. Crowding is often allowed in summer instead of thinning the canes early; fruiting canes, after the fruit is cleared, should be cut away at once, as this allows the new growth space and light to mature growth. Little winter pruning is necessary under these conditions, merely shortening the growth in March, or just before new growth commences; March is best, as if cut too early, and severe weather follows, the canes die down beyond their cut portion. As regards the height of canes left at pruning, much depends upon their strength, strong ones I have left from five to six feet. Feeding is an important item, for though the land may have been in the best condition at planting, food should be given freely after the first season, and if liquid manure from stables can be obtained so much the better, as it may be applied liberally. There is a great drain on the roots in light soils during dry seasons, and a mulch of cow manure is excellent early in the spring, followed by another as soon as the old canes are cut away.

The raspberry season can be extended up to the late autumn by growing such kinds as Belle de Fontenay and October Yellow, the two best autumn fruiters; these, like the other varieties, repay good culture, but they must be cut down to the ground in the spring, as the fruit is produced on the new growths, though not so freely as the summer varieties For summer fruiting Superlative is one of the best; Hornet is good, as also is Baumforth's Seedling, while a good white variety is Magnum Bonum.

CLIMBING ROSES FOR SOUTHERN GARDENS.

As climbing roses can be grown in southern gardens under so many pleasing forms of training, there is not a garden, even the smallest, but what some means might be employed to see them in full beauty, and, moreover, for one important reason, they should be selected in preference to the more massive hybrid perpetuals, as, by selecting suitable varieties, a longer season of bloom can be obtained from these than is possible to secure from plants whose growth is more restricted. Those who are anxious to plant a few climbing roses round their residence, or to cover pillars and archways, do not always make a wise selection, and are more often tempted to plant what will cover the given space quickly than to select probably less rampant growers, and more continuous in flowering.

Hence it is that we so frequently find the old favourites, Gloire de Dijon and Aimée Vibert, running almost wild over different positions which would make the finest possible sites whereon to establish some of the choicest varieties in the tender tea section, which are never seen in full beauty owing to the unnecessary and harmful pruning they are subjected to. The two varieties named above are not to be discarded—far from it; but it should be remembered that, beautiful as they both are when in full flower, their season is a very short one, and it is a mistake to allow them to occupy so much valuable space, and to exclude others which, in ordinary seasons, will give a wealth of buds for five months in the year; these, in my opinion, being more pleasing in shape, shade of colours, more fragrant, and in every way more useful for cutting.

Although not recommended for planting in all positions and localities, and at the same time admitting that it is not a perpetual bloomer, Maréchal Niel is still far away the finest yellow climbing rose in cultivation, and certainly deserves more attention than it receives. The pale small buds and puny foliage so frequently seen is the result of mismanagement rather than of constitutional weakness. It must also be admitted that fine vigorous trees sometimes collapse suddenly, causing much disappointment, and an unsightly blank space for some time; but we know fine trees in different parts of the country which are in the best possible condition. This we attribute to their being budded on the Gloire de Dijon stock, the young shoots being kept free from greenfly and mildew by early and frequent syringing, and not being overcrowded with small weakly growth, which in a great measure prevents the sun maturing the strongest wood early in the season. They also have the advantage of the roots being in a well drained border, which is kept in a sweet condition by an annual surface dressing of fresh loam, crushed bones, and wood ashes, and the exclusion of heavy dressings of rank manure in the autumn. The hardier hybrid perpetuals may revel in such dressings, but for the varieties under notice they either produce rank sappy growth, which does not become well ripened in the autumn, or render the soil unfit for many of the more delicate, but none the less beautiful, varieties. Next to Maréchal Niel, Cloth of Gold must be mentioned as an exquisite rose, but seldom grown because of its shy flowering habit. I would strongly advise any one to insert a few buds of this on an established but not over gross Gloire de Dijon. The growth made would be less vigorous than that produced on its own roots, especially if these had the run of a rich border. If it is found that flowering wood can be produced in this way, which we have proved can be, the shoots should be gradually increased, and those from the stock reduced. Among other varieties that may be selected for the purpose named are Madame Caroline Kuster, Rêve d'Or, Narcisse, Lamarque, Celine Forestier, Belle Lyonnaise, and Solfaterre. With the exception of Belle Lyonnaise these belong to the noisette section, and are of different shades of yellow, and as this colour generally denotes a certain amount of tenderness in roses, a south aspect or warm wall should be given them if possible. As yellow roses, when well grown, always command favour, we have formed a group of them, though those named do not exhaust the list by any means, and there are others that might be added.

Many of the varieties belonging to the tea section are most suitable for covering verandahs, arbours, and the like, as being allowed to grow at will, they not only cover these quickly, but as each new shoot produces a cluster of delicate buds, they might rightly be termed the true perpetuals. As an instance of this I may mention that we have growing against south walls several very large trees of Safrano, and there has hardly been a day throughout the winter but what we have been able to gather nice bunches of perfect buds. Of course, allowance has to be made for the locality and the unusually mild winter we have experienced, but I mention this to show what a natural free-flowering habit this variety possesses, and can therefore recommend it for a south wall or warm corner. Mention must also be made of Madame Lambard. In connection with this variety it is interesting to note what effect soil and position has upon the shade of the flowers; thus they vary considerably from creamy-pink to bright-rose sometimes on the same plant when the branches are trained round different angles of a building. It is certainly most desirable, and its glossy foliage is not so subject to greenfly as many others. Then there is that exquisite soft flesh-tinted variety, Catherine Mermet, which is most profuse in producing buds of the finest form, which, together with its pleasing colour and scent, makes it a favourite with all. We have had fine plants of this covering a south wall, and the blooms obtained late in October were quite equal to those gathered in June. It may be suggested that this is not a climbing rose. I admit it is not; but any choice variety which can be induced to throw the greatest amount of bloom by being allowed to occupy different positions generally given up to climbers of less merit, the object of the planter is gained, viz., a given wall space, pillar, or archway covered with healthy greenery, and abundance of fragrant blossoms. It is hardly necessary to recommend such well-known and general favourites as Homer, Climbing Devoniensis, Isabella Sprunt, Madame Berard, William Allen Richardson, and the like; but many more tender and beautiful kinds may occur to those who have failed with them in the open.

Goodwood Gardens. RICHARD PARKER.

VEGETABLES FOR EXHIBITION.

EARLY POTATOS.

UNDOUBTEDLY the potato (*Solanum tuberosum*) is the most popular and important vegetable cultivated in the kitchen garden, and indeed, in many farms where the soil is suitable, it now forms one of the [illegible] profitable crops. Nevertheless, much care and forethought is necessary to produce tubers of the highest quality even on the best land; there [illegible] be selection, preparation of the ground, proper planting, attention to the growing crop, lifting and storing, &c. Though popular and common as the potato is, I feel sure after long practical experience that both for general crops and exhibition my notes will prove interesting and useful to the cultivator.

We will commence with forcing for early supplies. New potatos are generally much appreciated in all establishments, and where means are available they should be brought forward as early as possible in the new year, and a continuous supply kept up till the outside crop is ready for lifting. For some years I have practised growing the earliest supplies in ten-inch pots, a very easy and simple plan; the pots can be moved from one place to another with little trouble, which is a consideration in the early months of the year. About the middle of December medium-sized sets should be selected of a suitable variety, and there are none better than Sharpe's Victor for this purpose. They should be placed in shallow boxes in a warm pit or greenhouse, fully exposed to the light on a shelf quite close to the glass but safe against frost. After the eyes have started, and the shaws grown to about one inch in length, they will be ready for potting. A light compost of two parts leaf soil and one each of old mushroom bed manure and light fibrous loam, all passed through a sieve with half-inch mesh, should be prepared and made nicely warm before using. The pots should be moderately drained and filled half full with the soil, on which should be placed two sets, carefully removing all the growths but two. Fill the pots three parts full, which will just cover the sets nicely, and leave room for earthing up after the growth has reached just above the top of the pot. They may be started into growth in any warm structure and in any part, but as soon as the growth is above the soil they must be placed in a position where the shaws can enjoy the benefit of the light, and an intermediate temperature only must be given them. A strong, sturdy growth should be aimed at, and in top-dressing them I have found nothing better than finely sifted old spent mushroom bed manure. Excessively liberal supplies of water must not be given at any time, but just sufficient only to keep them growing steadily. To finish them off they may be stood along the paths of a greenhouse, orchard house, or late vinery, and fine crops will be the result.

For a succession to the above grow a second batch in heated pits, or frames placed on hot beds of leaves and half spent horse manure thoroughly mixed together and turned several times. Before forming the bed allow all the rank steam to escape, after this the frames may be placed in position upon the fermenting materials, but the soil in no case should be added until it is quite certain that the bed is in a sweet condition, and that the heat is on the decline, otherwise the compost will become baked and worthless. I much prefer deep brick pits with a flow and return of two-inch hot-water pipes running all round near the glass. The bottom part should be filled with leaves, oak or birch if possible, and when the heat from these is on the decline a good light compost should be spread over the surface to the depth of about a foot, allowing plenty of room for the tops to attain full development without coming in contact with the glass, as in very severe weather, even with the aid of hot water pipes, the foliage may become damaged. The sets should be prepared exactly as advised for pot culture, and many varieties are suitable for this planting. My favourites, however, are Sharpe's Victor, a good type of Ashleaf, and Snowdrop, the latter a very excellent kind for pit and frame culture. A little more room [illegible] required between the rows for the last named than for the others, eighteen inches being necessary, and fourteen inches from set to set; [illegible] Ashleaf and Sharpe's Victor may be planted fifteen inches from row to row and twelve inches apart in the rows. They should be covered to the depth of about three inches, and in large establishments successional plantings should be made in this way about every ten days. It is a good plan to have a crop of radishes in each plantation. If sown between the rows no harm will be done to the potatos, and very excellent radishes are obtained in this way as they will be drawn in time to allow the potatos to be earthed up, which should be done with the same kind of compost as is used for planting. Little other attention will be required except careful ventilation and judicious watering. Too much fire heat [illegible] be employed or the growth will be weak and drawn. In the case [illegible] beds much more attention is required and additional fermenting [illegible] needed around the frames as may be necessary to maintain a [illegible] heat. Efficient covering of the glass in severe weather is necessary, as nothing is more tender than the potato, especially when forced. [illegible] excellent tubers for exhibition are generally obtained from these plantings for early shows, and, each day, when lifting all the most [illegible] tubers should be carefully placed on one side, and as quickly as [illegible] put in boxes and covered with some of the soil in which they [illegible] been growing and kept till wanted. The less they are exposed [illegible] the air the fresher and better will be their appearance on the [illegible] table.

Unless an unlimited amount of glass is at command some other [illegible] must be resorted to for keeping up the supply till the outside crop [illegible] ready for lifting. Turf pits on a south border, rough wooden pits [illegible] eight feet in width, which any handy labourer can make, or [illegible] the foot of a south wall, will be found convenient. In either case, [illegible] protecting material can be easily placed over them during frost or [illegible] cutting winds, and if the soil is properly prepared, splendid potatos, both for home use and for exhibition can be obtained in this way.

For the earliest crops in the open the ground should be thoroughly trenched during the autumn, but not manured. The soil should be left in quite a rough, lumpy state on the surface, and a warm, sheltered part of the garden, such as a south border, should be chosen. Early in March the sets, which should have been previously selected and prepared, may be planted. Numberless varieties are now in existence suitable for early crops, and very many are well adapted for early supplies; most people have their favourites, though Sharpe's Victor and Ashleaf, both of very excellent quality and quick to mature, will be hard to beat. It is advisable to plant at a depth of at least six inches. A good trench should be taken out, and a layer of spent horse manure and leaf soil be placed in the bottom. The sets should be planted on this at a distance of fourteen inches apart, placing a good portion of the same mixture over them. Over this again should be drawn the soil taken from the trench, a line being stretched along the centre and a mark made down the row. This will be of service in hoeing over the ground to clear it of weeds, if necessary, before the shaws are through the ground. An enthusiastic gardener will be constantly on the watch for the young growth as everyone knows how very tender the potato is, and on the least sign of frost they should be carefully examined during the day, and a little soil drawn over them. Frequent hoeings should be made, as this keeps the soil light and open, as well as freeing it from weeds. When the growth is too high for covering with soil and the weather is at all uncertain some material must be used for protecting growth, such as spruce branches, long litter, old tiffany, bracken, or, if nothing better can be obtained, rhubarb leaves will keep the haulm safe during a rather severe frost. No time should be lost in thoroughly earthing them up, as the comparatively loose soil will afford them much protection. This is best done with a draw hoe when the tops are about three inches above the ground. The ridges should be left neat and straight, and nothing more will be required till lifting time comes round. The same care should be taken with the most promising tubers as previously advised if required for exhibition. They should be handled most carefully, must not be rubbed or bruised in the slightest. Splendid specimens are often found in these plantations. A successional planting should also be made about the middle of the month.

Aldenham House Gardens, Elstree, Herts.

STABLE VERSUS MOSS-LITTER MANURE.

A question is asked by A. D. on page 99 regarding the relative values of ordinary stable or straw manure and moss-litter manure. Farmyard manure differs from moss-litter manure in several important particulars. The quantity of straw employed as litter must necessarily affect the general composition of fresh dung, and more especially the amount of moisture which it contains. The greater the amount of liquid manure it can be made to absorb the larger will be the heat developed. In fresh dung the proportion of organic and mineral substances is small; this circumstance fully explains the slow action of stable manure when compared with the effect which well-made moss-litter manure—containing, as it does, more both of the solid and liquid excrements of the animals—is capable of producing.

The proportion of insoluble matters, more especially of insoluble organic matters, in fresh dung, on the other hand, is very large, and considerably exceeds those of moss-litter manure. The total amount of nitrogen contained in the soluble portion of fresh dung likewise is inconsiderable. Most of the nitrogen, which is gradually liberated as the fermentation of the dung progresses, is contained in the portion of the manure which is insoluble in water. In other words, comparatively speaking, little nitrogen exists in fresh dung in a state in which it can be assimilated by growing plants; while in moss-litter manure, owing to the large amount of carbonate of lime present (an ingredient of the peat moss), the nitrogen of the excrements becomes rapidly converted into nitrate of lime, and is assimilated by plants at once. For this reason the staying powers of moss-litter manure is less than straw-litter manure, weight for weight. Also the nitrogen which is not at once taken up by the growing plants is wasted by drainage. Therefore it is that although moss-litter manure may originally contain more nitrogen than the straw-litter manure it does not last so long, nor produce the crop effects which one would be led to expect.

Again, moss-litter manure is very poor in alkaline salts, especially of potash, since these substances have been in great part washed out by the water covering the peat deposits. The principal constituent of the soluble ash of fresh dung, on the other hand, so far as quantity is concerned, is potash. One hundred parts of soluble ash contain no less than thirty-seven parts of real potash, or a quantity which is equal to fifty-four parts of pure carbonate of potash. Straw-litter manure also contains a large amount of soluble silica, both in the soluble and in the insoluble ash. This is practically lacking in moss-litter manure. In the soluble ash this silica is united principally with potash. Fresh farmyard or stable manure made with straw as litter contains much soluble silicate of potash, which is especially valuable in the growth of plants.

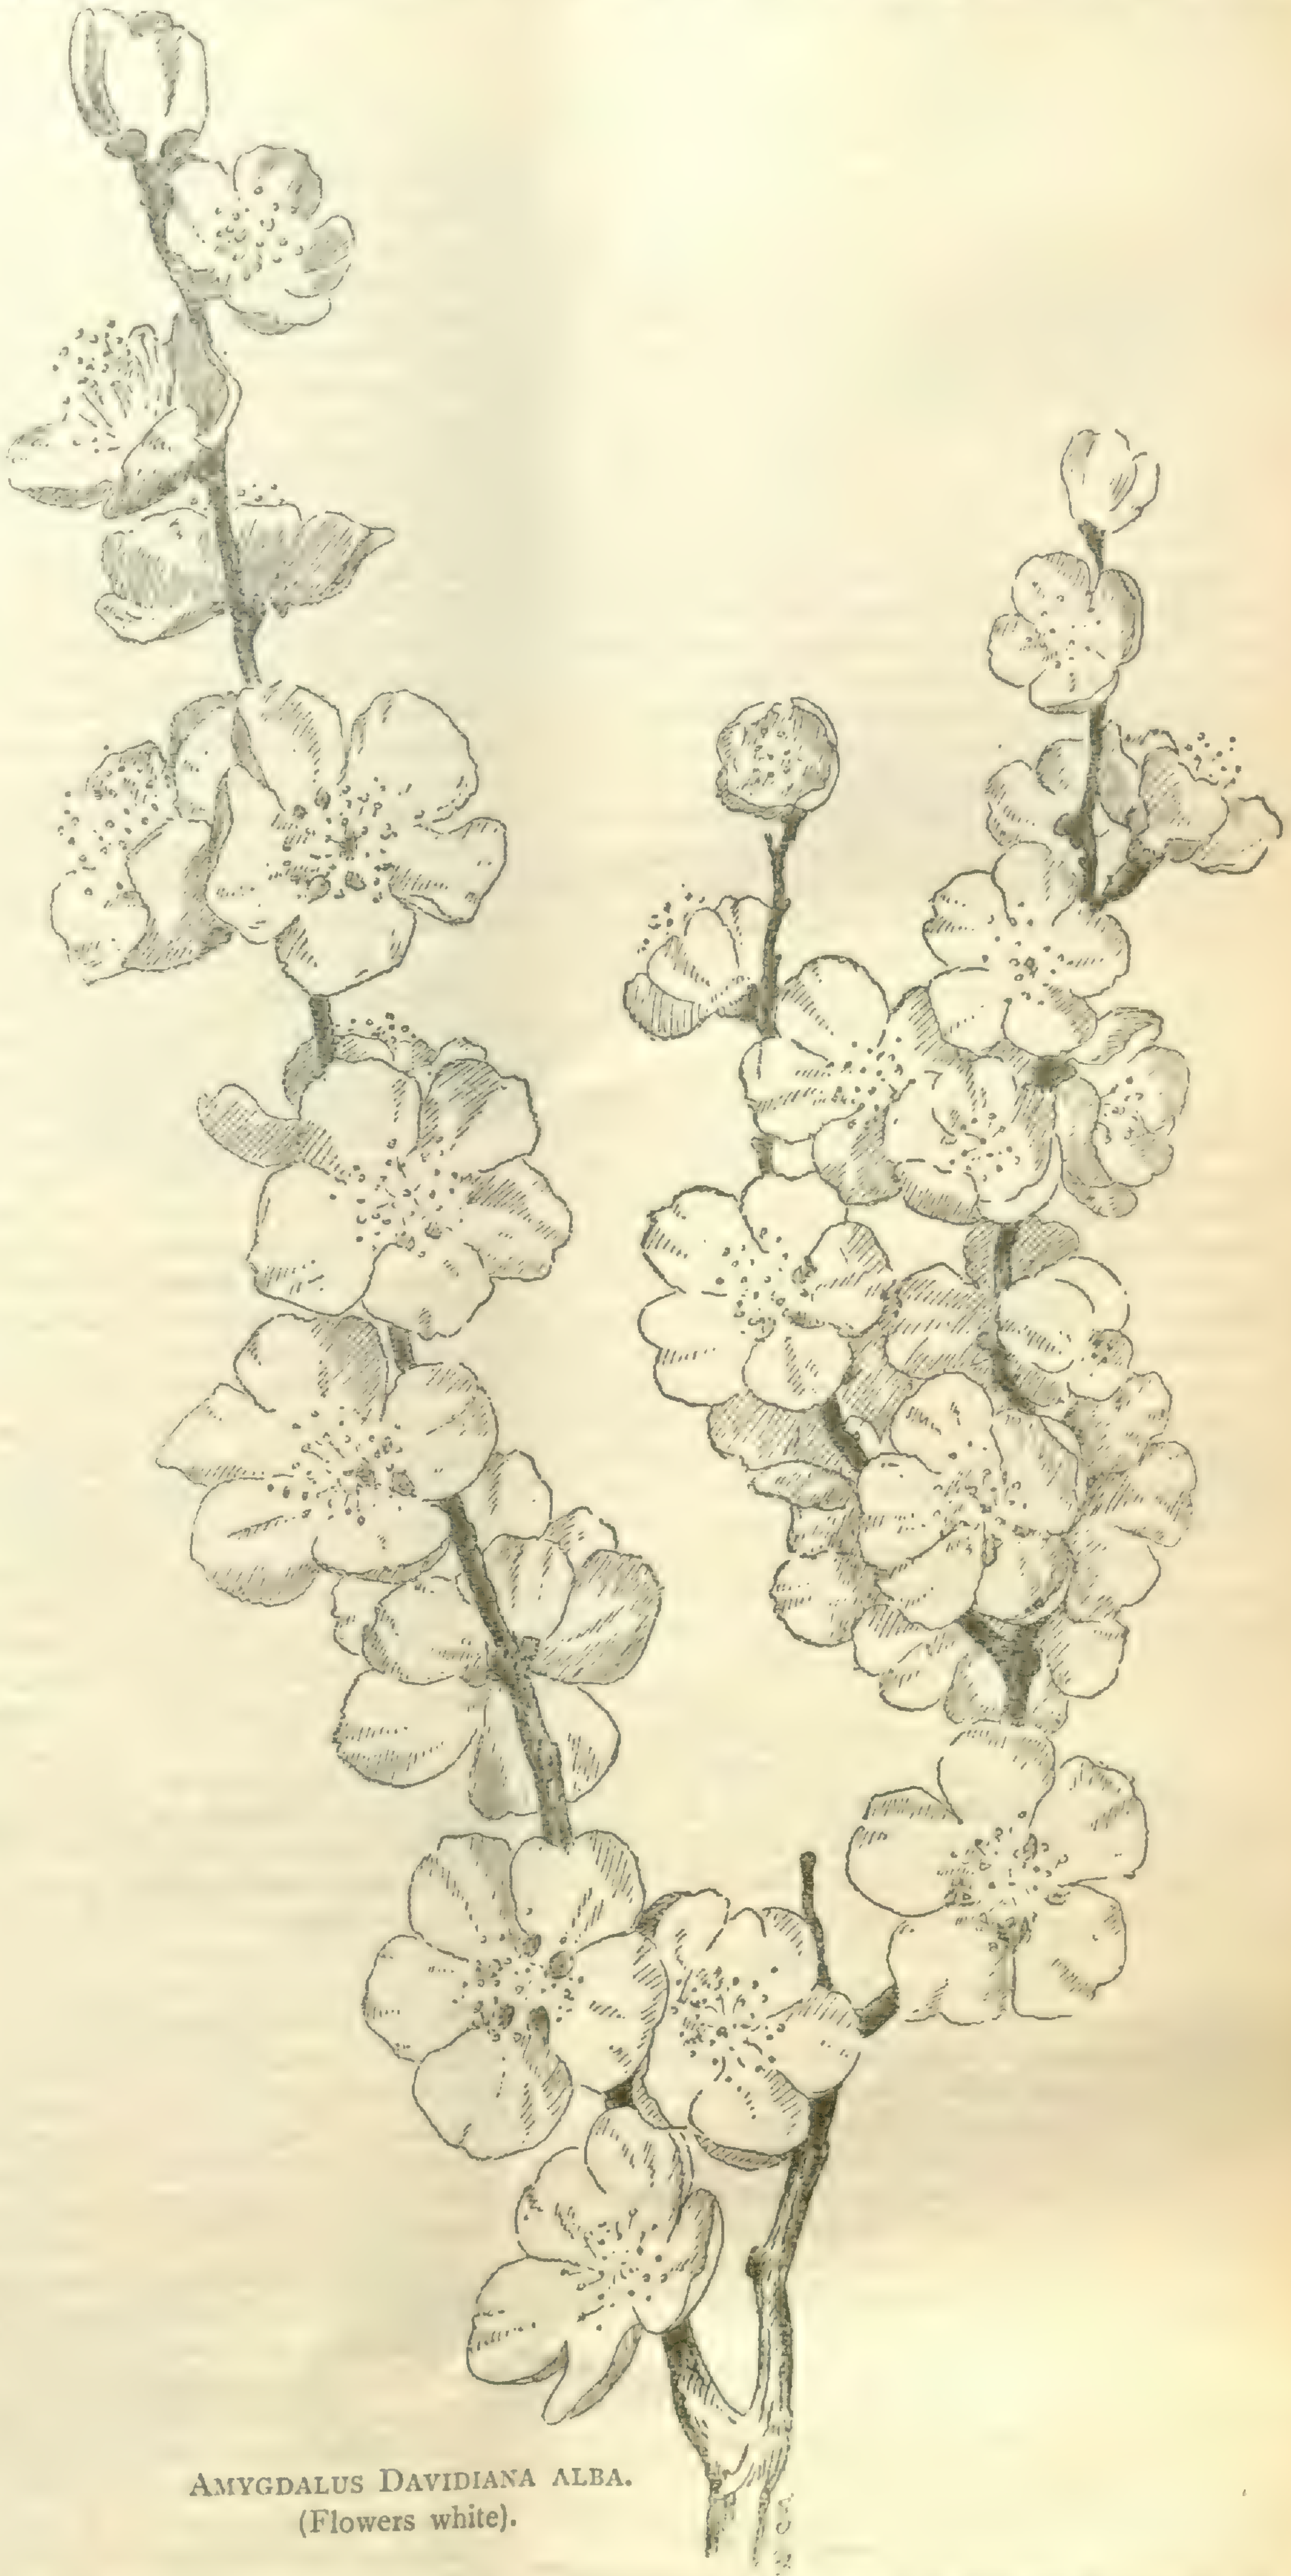
Harpenden.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book,' containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[Advt.]

AMYGDALUS DAVIDIANA ALBA.

The almonds are noted for their extreme beauty and their precocity, for they are among the earliest of flowering trees to brighten up our gardens. The common almond is one of the most elegant of trees when smothered in pinky white blossoms, and already in the more favoured London suburbs its blossoms have expanded under the genial influence of the recent bright sunshine. Far in advance of the common or sweet almond, in time of flowering, is Amygdalus Davidiana, a Chinese species, that commemorates that intrepid collector, the famous Abbé David. This is still a comparatively scarce tree in all but the gardens of the most advanced horticulturists, but considering that it commences to unfold its blossoms ere January has passed, and is soon clothed in white rose-tinted flowers it deserves to be more popular. The species was first brought before the horticultural community by Messrs. J. Veitch and Sons, who exhibited on March 8, 1892, and gained a first-class certificate for it. A pure white variety is now available, and forms a beautiful companion to the type; this we figure in the present issue, and the illustration serves to show how freely both variety and species produce their charming flowers. Having regard to the early date at which this almond blooms intending planters should provide a sheltered position for their specimens so that the crop of blossoms may not be injured by cold frosty winds following rain or snow.



Amygdalus Davidiana alba.
(Flowers white).

AMONGST THE CHRYSANTHEMUMS.

THE somewhat monotonous and tedious process of propagating a large collection is perhaps the least troublesome, though it is decidedly the least interesting period of the year's work amongst chrysanthemums. Growers will welcome the advent of brighter weather and longer days equally as much as the plants themselves, and these latter will now rapidly gain vigour and develop a sturdy, healthy growth.

In the routine of watchful attention which these plants constantly require nothing is more important at this season of the year than a full exposure to light, a position near the roof glass, and abundance of ventilation whenever possible without admitting cold, cutting winds directly on to the plants. Any treatment which deserves the name of "coddling" usually ends more or less in failure; a close, moist atmosphere with a high temperature is altogether wrong treatment, and quickly induces a thin, long, and weakly growth. A temperature ranging between 40 and 55 degrees will suit the plants admirably. The higher figures should only be approached by the aid of sun heat, plenty of ventilation being given when the thermometer records 50 degrees. Watering is very easily managed, though extremes must be avoided; too much is as injurious as too little; an occasional sprinkle overhead on mild bright days during the forenoon may be given with advantage, but no liquid manure is needed by the roots at this period, as feeding will promote a soft, fleshy growth which will not bear the exposure to open air treatment later on. Firm and robust health with dwarf short-jointed growth is the ideal condition, and may be easily maintained if a good loam is used in potting. Freedom from insect pests must be secured, and these are very easily kept in check whilst the plants are inside by using the now well-known nicotine vaporising compound, which has made the work of fumigation such a simple matter. Green and black fly and thrips are troublesome at this season. A light dusting of soot amongst the plants is a great help in keeping away insects.

Potting must be done as soon as the roots require more room, and this is easily determined by carefully turning a plant out of its pot; no better rule can be given, and it is most unwise to defer this operation when once the roots have thoroughly occupied the soil in which they are growing. The question of soils always appears interesting, and many beginners suppose that herein lies the whole secret of successful cultivation. I grant this is an important point, but not more so than many other details of apparently less consequence. A good loam is the chief essential in mixing a suitable compost, and that is the top three or four inches of old pasture land which is medium in character, between clay and sandy soil, and which necessarily contains abundant grass-root fibres. This is best when dug and stacked some few months before it is required for use. Two-thirds of such loam, and the remainder equal parts leaf-soil and well-decayed stable manure, adding a good sprinkling of sand and wood ashes sufficient to keep the soil sweet and open, make a suitable compost. Be sure the roots are not dry when potting takes place, and the new soil should also be in a nice medium condition as to moisture; pot firmly to ensure a steady growth, for if the roots penetrate too quickly into the new soil the top growth will be also rapid and thin. Firm potting conduces to the dwarf, sturdy growth we so much desire. Though it is generally correct to root the cuttings in December and January in order to give the plants a long, steady growing period, some of those varieties which bloom early, such as Australian Gold, Mutual Friend, and Pride of Madford, will give excellent blooms if good cuttings are taken late in February and grown on in the usual way, taking only two blooms from each plant. By propagating thus late the flowering period is retarded, which, in the south of England, is an advantage to exhibitors, as it is difficult to preserve blooms of some varieties in good condition for November shows unless such methods are adopted.

We are experimenting this season with several varieties with respect to retarding, as I am much inclined to believe that early propagation is unfavourable to some, and the variety which has led me to this opinion most of all is Reine d'Angleterre. In 1895 we had one small cutting of this in March, and the resulting plant gave us three excellent blooms, whilst in the two succeeding years, though we have had apparently better, because stronger, plants from cuttings taken in December the flowers were quite moderate. The blooms from the early rooted plants were from second crown buds, whilst those from the March cutting were from the crown buds. In the former case the crown buds appeared too early (about July 25), to be taken, and the same bud on the late struck plant was taken on August 12, thus proving the influence of late rooting over the time of formation of the flower buds. This suggests another point in the successful treatment of some varieties, but with the numerous introductions each season, it is only reasonable to suppose that those varieties which give us good blooms at the proper time are the ones most likely to become popular. It occasionally happens that a really splendid flower of a comparatively little grown, though by no means new variety, is exhibited in a collection, and, usually, this is observed at provincial shows. Such blooms are, undoubtedly, the result of a certain peculiarity of treatment which the plant has received, it may have been in the time of propagation, in pinching, or in the accidental breaking of a shoot which has been the means of bringing the flower bud at just the right time or occasionally in the exceptionally early formation of the bud which controls what is known as the natural break. As a consequence of this one fine bloom a great many people are induced to try the variety again with usually failure as a result of their pains. It would be a great benefit to growers if those who are successful with particular varieties would record their treatment, instead of leaving others to find out as best they can. The narrow-minded age of secrets and mysteries, at least in gardening matters, has surely gone past, and each of us to be really successful in our calling must give and take of our experience freely.

Young plants from nurseries need careful handling when first received, and it is best to keep them moderately close for a day or two in case they have been grown in warmth as a sudden change to quite cool treatment would injure, or, at least, check the growth. I am afraid the disease which was observed amongst chrysanthemums last season for the first time in this country will prove troublesome. It very much resembles the fungus which attacks carnations and is, perhaps, identical with it. I am making inquiries about it amongst friends, and will shortly send our editor the result.

Trent Park Gardens. W. H. LEES.

SUNDEWS.

THE plants that may be included under this heading comprise the genera of drosera—the true sundews—roridula, drosophyllum. By far the largest genus is drosera, the members of which are natives of Australia, Cape of Good Hope, and North America, and three British species. Roridula contains but two species, one of which, R. gorgonius, is now probably the only representative in cultivation, while the genus drosophyllum, a native of Portugal and Morocco, is monotypic. Of the droseras, two of the strongest as well as most handsome are D. dichotoma and D. binata, the former being by far the strongest grower, with the leaves twice branched, and with less highly-coloured tentacles than in D. binata, forming a plant of twice the height of the species last named, of which it is considered a variety. The North American species, D. filiformis, is extremely attractive when grown in mass, but has a habit of dying out under cultivation after a few years. D. capensis (figured in the GARDENERS' MAGAZINE, April 15, 1893), is one producing a stem of three or more inches high, bearing persistent foliage, its specific name indicating its habitat. D. spathulata and D. Burkei closely resemble each other, forming close tufts or rosettes of foliage, with exceptionally bright red tentacles. A very slender plant is D. auriculata, from Australia and New Zealand, with a stem nine inches high and small ear-shaped blades; upon short petioles. Our native species are not the least interesting of these plants, and I have seen quite nice specimens of D. rotundifolia grown in saucers in dwelling rooms. D. anglica and D. intermedia possess spatulate foliage, and are both British. A few years ago D. cistiflora was attracting considerable attention at Kew on account of its rosy red flowers, but is, I believe not now in cultivation.

The long linear leaves and tentacles possessing no power of movement, though the secretion is extremely profuse, at once distinguish the genus drosophyllum from the foregoing. This grows a foot or more high, and has primrose-yellow coloured flowers. Seeds germinate freely of this plant, and it is best grown in a compost of fibrous loam, broken rocks, and sand. Roridulas are most energetic in their fly-catching habit. At the Cape they are of bush-like habit, of several feet in height, and are said to be hung up in the dwellings as we hang fly papers, being taken down and rinsed after a good catch. This we find succeeds fairly well in a greenhouse temperature in a sandy peat soil. The above are most of those in cultivation, and when well grown they cannot fail to be of interest, not only on account of their insectivorous habits, but as ornaments to our greenhouses. They are now commencing growth, and preparation should at once be made for their being attended to in the way of potting or renewal of soil, if necessary, in whatever manner they are grown. They are in no way difficult to cultivate, and all will grow in a cool greenhouse temperature in a compost of fibry peat, chopped sphagnum, moss, and coarse sand; or if the beds are of any dimensions some broken charcoal may be added.

The droseras are lovers of a boggy soil, in which large quantities of water are present, and, indeed, this is the case with both roridula and drosophyllum, both requiring copious supplies in their growing season, though during the winter a less supply is necessary for these two latter genera.

If grown in pots it is a good plan to cover the stages with sphagnum, upon this the plants may be stood upon inverted pots. In this way, if they are examined, fine healthy roots will be found to have grown into the damp hollow chamber formed by the hollow pots—to the length of several inches, all exceedingly healthy, and covered with fine root hairs. Taking this into consideration, they are now grown here in a house specially prepared for them, by having tanks of shallow depths—about a foot—a space of a few inches being left at the bottom by planting them upon a teak staging or raft. In this manner the roots will during the growing period find an unlimited supply of moisture when necessary—as the bed can be saturated at will, or be kept dry if needed, as the tanks may be filled or emptied at any time. All are lovers of sunshine, and by full exposure a fine red tint is obtained upon the tentacles, which adds distinctly to their appearance. Although enjoying a superabundance of moisture, on no account must they be syringed, as this causes the glands to run, as well as knocks one leaf against another, sticking them together, and giving them a very draggled look.

Edinburgh. R. L. HARROW.

Late Chrysanthemums.—The chrysanthemum L. Canning seems to come in for an equal share of praise and abuse. After considerable experience I find it the latest and also the shortest lived of all the varieties when cut, and for the latter reason I cannot recommend it. The plants seems to be very subject to mildew, and are scarcely presentable when used in pots as single specimens for filling vases. I can thoroughly recommend Princess Victoria, which has creamy-white flowers; the foliage is grand, and the blooms last, when cut for large vases, for two or three weeks, according to the position and temperature of the room. When grown as a bush and kept in very cool quarters when housed, it certainly runs Canning very close for lateness. I cut the last blooms of it on Saturday, February 5, for use in a church, where they are still good at nearly the end of the month. Both the varieties are fine when grown in five-inch pots, and I think L. Canning beats the Princess when grown in this manner. The method I have tried answers admirably. Take a number of the tops from the stock grown for bushes during the last week in May, and strike them in heat; pinch out points of same when rooted, so as to induce three or four shoots; pot on to five-inch pots, disbud and leave one bloom on each shoot. The result will be some useful decorative material.—A. JEFFERIES, *King's Walden Bury.*

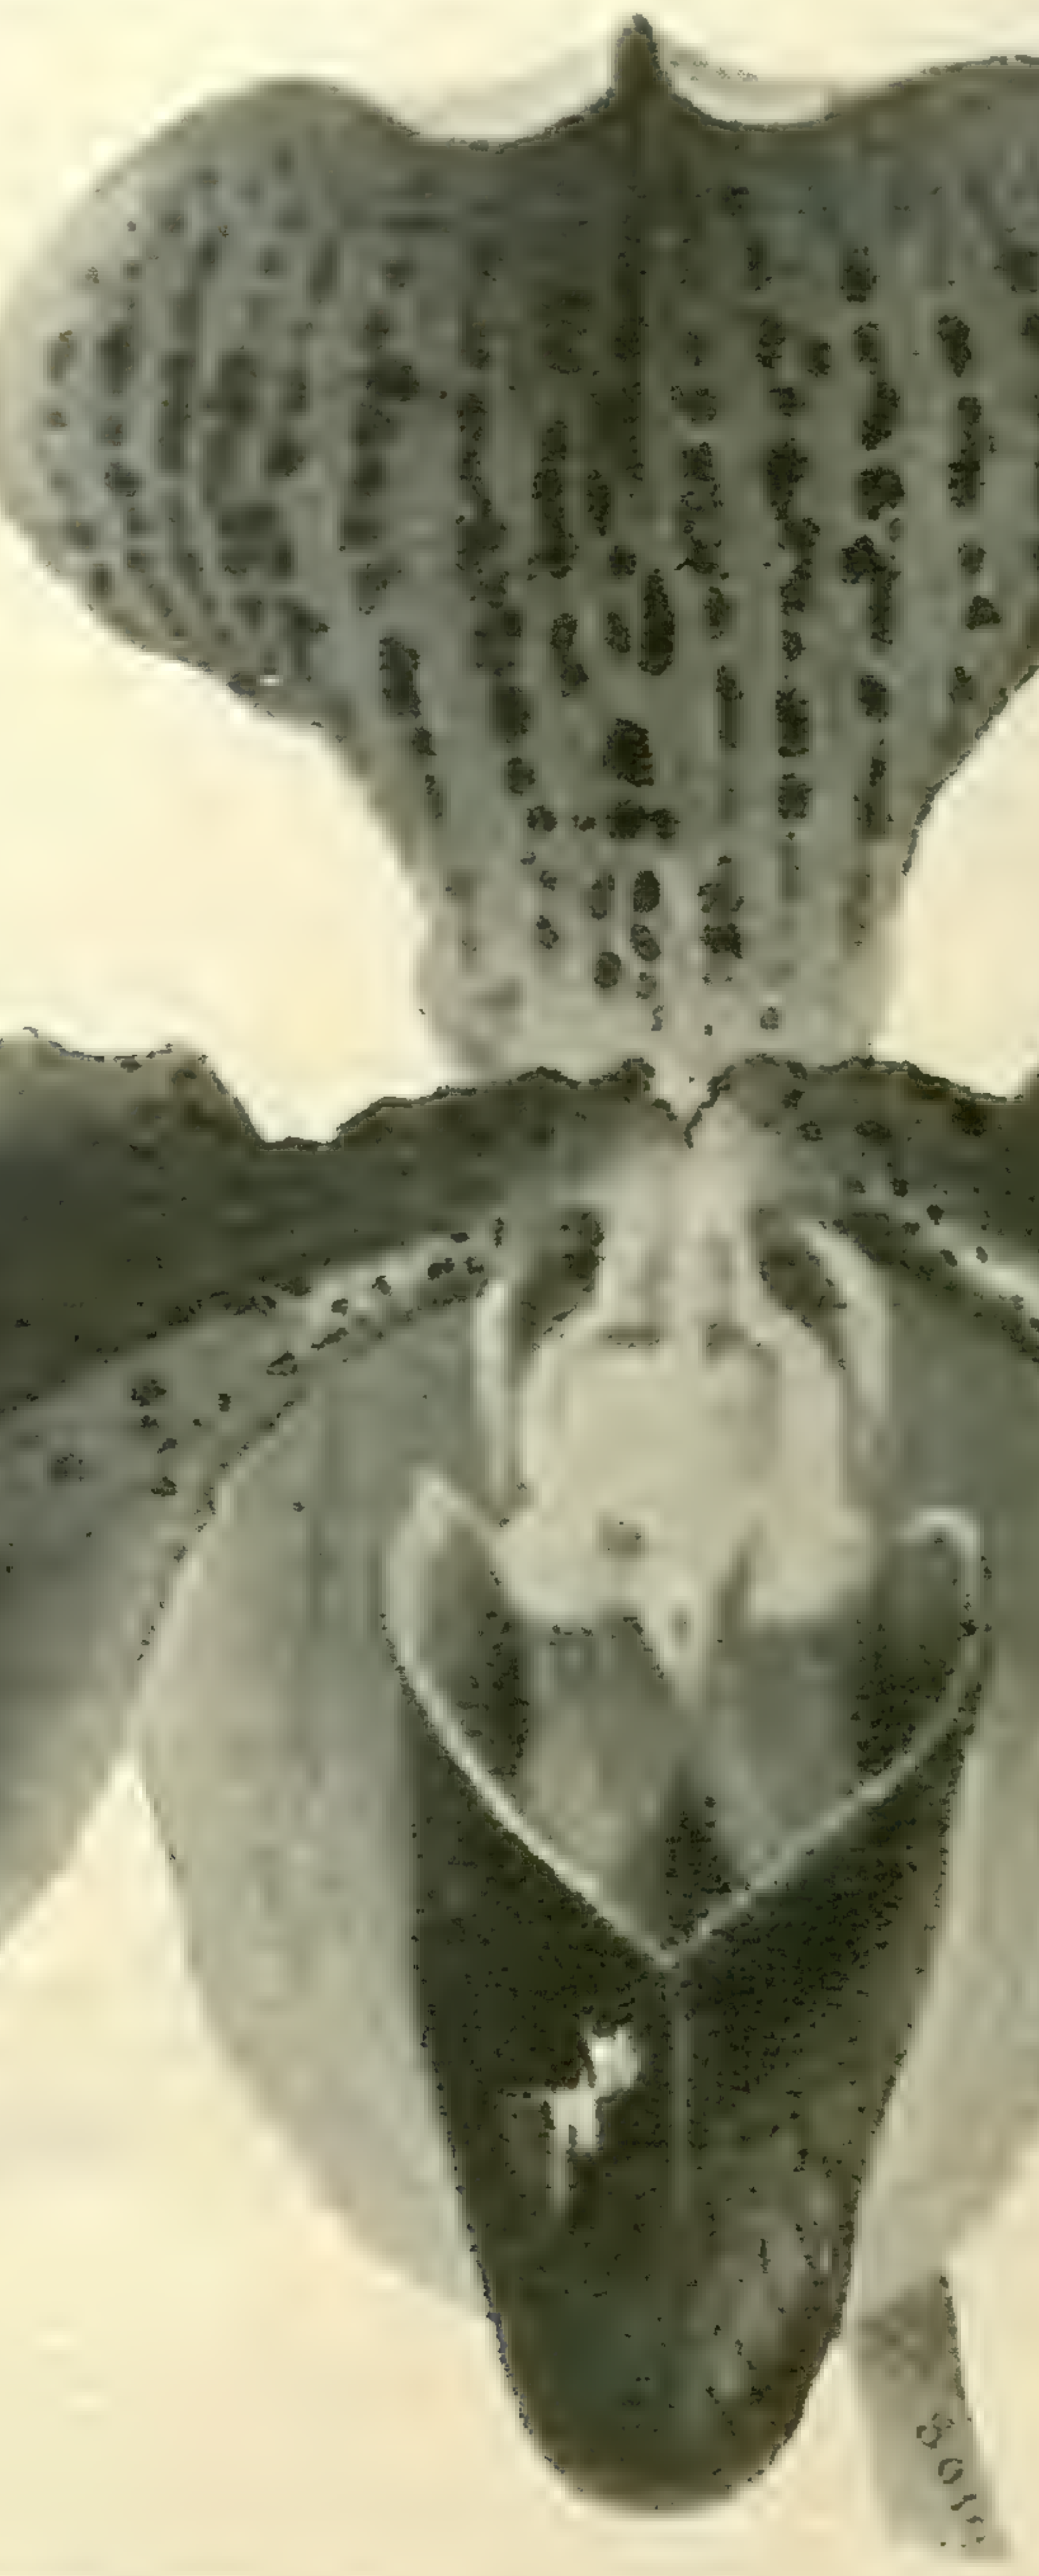
HYBRIDS OF CYPRIPEDIUM BELLATULUM.

AT the present time this section of the cypripediums is the most fashionable of any of the Lady Slipper orchids. Since writing my notes—published in the GARDENERS' MAGAZINE, vol. xxxix., p. 794—there have been several remarkable additions to the group, and one of the most interesting to botanists has been the raising of Cypripedium Godefroyæ by artificial hybridisation. A seedling flowered in the collection of G. W. Law-Schofield, Esq., New Hall-Hey, Rawtenstall, which had originated in Sir C. Strickland's collection; the parents were C. bellatulum and C. niveum. The seedling proved identical with C. Godefroyæ, and this was a most gratifying result. Some five years ago one of the most prominent of our orchid authorities paid a visit to the collection of which I have charge, and I drew his attention to the possibility of the form known as C. Godefroyæ leucochilum being a natural hybrid. The intermediate characteristics, both in growth and flowers, clearly indicating the possibility of a natural hybrid between the two species named above. Then another form imported with the white-lipped variety gave every indication that C. concolor was instrumental in its production. The growth, however, is broader and more clearly tesselated, while the lower sides of the leaf are considerably less purple than in hybrids where there are indications of C. niveum. The flowers, instead of having a white ground, are in some cases a rich golden-yellow, in others considerably paler, but having decidedly C. concolor characteristics. The specialist protested, and pointed out the apparent impossibility of such a result, owing to geographical distribution, notwithstanding the fact—as I pointed out at the time—that we had flowered from the same case of plants C. niveum, C. bellatulum, C. concolor, and the two forms referred to above. He was, no doubt, considerably impressed, and, judging from a statement made at the Drill Hall in respect to the flowering of C. Godefroyæ from seed in our own gardens, he is now satisfied that the geographical distribution of this section was not so wide as was imagined. There can be no doubt in future that C. Godefroyæ must be classed as another addition to this growing family of natural hybrids. The variety C. Godefroyæ leucochilum was introduced through Messrs. Walter Kemsley and Co. about six years ago, the first importation being procured by and divided between the two brothers Messrs. R. I. and R. H. Measures. From the collection of the former several remarkable forms have been exhibited, one of which gained the F.C.C. of the Royal Horticultural Society.



CYPRIPEDIUM BEECKMANI. (Flowers green, white and bright purple brown.)

One of the most prominent of the C. bellatulum hybrids that have been introduced during the past eighteen months is C. Rolfeanum, said to be the result of crossing C. bellatulum and C. Rothschildianum, but no indication of the latter parent was observable when the plant was exhibited at the Drill Hall, and there is, no doubt, some mistake in the records; the spotting and general characteristics of the flower indicating that C. Leeanum, or some other variety in that way, had been a parent. It is, however, a most distinct and desirable hybrid, and is worthy of cultivation. C. Enid (C. bellatulum crossed C. Spicerianum) was raised in the nurseries of Messrs. J. Veitch and Sons; the flowers are most distinctly marked, but they are considerably smaller than in many of the beautiful hybrids of this section. It is, nevertheless, a distinct and desirable form, which will, no doubt, improve as the plants gain strength. Another fine form that flowered with the same firm is C. Measuresæ Veitch's var., and it is one of the very best of the C. bellatulum and C. Veitchi hybrids. It was exhibited last year at one of the Manchester and North of England Orchid Society's meetings, when it was adjudged worthy an award of merit by the committee; it was exhibited from the collection of G. W. Law-Schofield, Esq., by the gardener, Mr. Shill. There is no doubt the finest hybrid cypripedium of last year, and equal, if not superior to, the best of its predecessors, was C. Chapmani magnificum, which gained a F.C.C. at the Temple Show of 1897. The dorsal sepal is upwards of two and a half inches in breadth, over two inches long, creamy white, heavily suffused with rose-purple and thickly spotted in lines with deeper purple, these spots increasing in density toward the base; there are some traces of yellow in the centre near the apex. The petals are upwards of two and a half inches in length and one and a half inches broad, creamy-white, heavily suffused with bright rose, and thickly covered with large, deep purple spots. The lip is rich purple shading to greenish-white at the base. This variety was raised in the collection of R. I. Measures, Esq., at Ladymead, East Harting, Sussex, by Mr. Wotton, and is the result of crossing C. bellatulum with the pollen of C. Curtisi, and is, therefore, the reverse cross of the original C. Chapmani.

The subject of the accompanying illustration, C. Beeckmani, is a continental hybrid said to be the result of a cross between C. Boxalli superbum and C. bellatulum. If this parentage is correct the plant is certainly a remarkable freak, for there is not the slightest indication of tesselation in the foliage as seen in all other C. bellatulum hybrids, and the foliage also, instead of being dwarfed by the influence of the latter species, is certainly longer and much more robust than in C. villosum Boxalli. The flower also has not the slightest trace of C. bellatulum, although it was the opinion of some who saw it that the spottings on the lower sepal and the purple at the back of the upper sepal were derived from that species. These spottings were, no doubt, derived from C. Boxalli, as they are prominent characteristics of all the very best forms of that species. When exhibited by Messrs. Linden and Co., of Brussels, at the R.H.S. meeting on November 22 last it was adjudged worthy of an award of merit by the Orchid Committee, who considered the recorded parentage so doubtful that they were unable to accept it. C. Beeckmani is, nevertheless, a remarkably fine cypripedium, and worthy of being included amongst the very best. The dorsal sepal is green thickly spotted with brown at the base, and having a broad margin of white at the apex. The broad, finely-shaped petals, green in the lower halves, and suffused with brown, have the upper halves pale green spotted with dark brown at the base, and becoming wholly suffused with dark brown at the apex. The lip is highly polished brown shading to greenish white. The gigantic proportions and fine substance of the flower should be sufficient to recommend this to all lovers of cypripediums. It is after the style of C. Lucianum, which was also exhibited as a C. bellatulum cross, but it is altogether superior to that hybrid. It evidently belongs to the class requiring the cool-intermediate house treatment, such as I find suits C. villosum and C. Boxalli crosses better than that afforded by warmer houses.

Cambridge Lodge Gardens. H. J. CHAPMAN.

NITRATES, AND THEIR USES IN THE GARDEN.

It is rather an interesting fact that the importance of nitrates for plants has long been recognised ; also that the growth of plants is considerably promoted when this element of food is present in the soil. Nitrous food may exist as nitrate of potash, nitrate of lime, nitrate of soda, and nitrate of ammonia. Recent investigations have established the fact that for most green-leaved plants the nitrates are capable of supplying all the nitrogen which is needed for their growth. Nitric acid, therefore, may be regarded for all practical purposes as the final form of nitrogen for most horticultural plants, and that all other forms must first be converted into it ere they become available as plant food. Even ammonia must be converted into nitrates before plants can use it.

When nitrate of soda, or any of the other nitrate compounds, is used as manure, its nitrogen does not enter into fixed combinations within the soil, but nitrate is dissolved in the soil water, and unless taken up by vegetation, much of it passes into the drains or into the subsoil beyond the reach of the roots of the plants. When salts of ammonia are used as manure, part of the ammonia is temporarily taken up by the soil, but it is more or less rapidly (according to the character of the soil, and of the season) converted into nitrates, and is then subject to loss by drainage, as when nitrate of soda or any other nitrate is used.

A ton of farmyard or stable manure will rarely contain more than from ten to fourteen pounds of nitrogen, and that in an organic form. Now plants are unable to feed upon nitrogen in an organic form—that is to say, in the condition in which it exists in the decaying matters of soils and of farmyard manure. Such organic nitrogen only becomes useful for plant food after it has been converted into nitric-nitrogen or nitrates by a process more or less slow and interrupted, which is termed "nitrification," and which will only take place in the upper layers of the soil when there is a plentiful supply of atmospheric oxygen ; a certain amount of warmth and moisture are also necessary, as well as the presence of organic matter, lime, and certain other mineral ingredients. That in proportion as those conditions are fulfilled, so will be the rapidity of its development. The absence or presence in excessive quantity of water or organic matter will prove fatal to nitrification.

If a soil contains a very large percentage of putrefying organic matter nitrification will not take place, for the reason that so long as there is such a demand for oxygen, the air present in the soil will be all used up in oxidising the organic matter. This is why nitrates will never be found except in the merest traces in fresh farmyard or stable dung, or in old kitchen garden soils very rich in organic matter. In general, it may be said that an abundant supply of phosphoric acid, potash, and lime tends, in plants, to increase fruitfulness, hardness, and firmness of stems and leaves, while an abundance of nitrogen has a tendency to produce luxuriance of wood and foliage. But while plants cannot be at their best without a suitable supply of nitrates, it is an important fact to remember that those plants which are grown chiefly for their flowers and fruits may be easily injured by an amount only slightly exceeding a sufficiency.

Thus, when certain crops, such as those of the cabbage tribe, lettuce, asparagus, potatos, onions, parsnips, celery, beet, rhubarb, ferns and foliage plants, &c., which are valued mainly for their stems and leaves, are considered, there may be no danger from an abundant supply of available nitrogen, always provided the mineral constituents are not deficient in the soil. On the other hand, plants that are raised for their flowers and fruits exclusively should be liberally fed with mineral ingredients, especially potash and phosphates, and with but a minimum quantity of nitrogenous food.

In one sense farmyard or stable dung is the best of all manures for the garden, because it is a safe and a complete manure, bringing to the soil, together with the mineral substances indispensable to the nourishment of the plants, the organic matter which, when changed into humus, is of such value in mellowing the surface soil. It also allows an excess of moisture to pass easily away, while in dry seasons the humus assists in holding a supply of moisture till the rain comes.

It has been explained that the nitrogen of manure must be changed into nitrates before it is available as plant food. For the growth of early vegetables it is found necessary to use enormous quantities of manure, far in excess of the amount of plant food removed in the crop. Gardeners who make a speciality of growing large areas of early cabbages, potatos, turnips, lettuce, rhubarb, &c., find it almost impossible to make the land rich enough the first year. They find the second or third crops grown and manured every year on the same land, are better and earlier than the first crop ; this is owing to the slowness of the formation of nitrates that takes place in the manure.

For early potatos as much as forty tons of stable manure and ten cwts. of artificial manures per acre, the latter consisting of guano, dissolved bones, superphosphate, and kainit salt, are frequently used, and only about four or five tons of produce is obtained. While for a late crop of potatos, the manure may range from fifteen to thirty tons, with from eight cwts. per acre of artificial fertilisers, and the crop obtained may average six to eight tons of tubers per acre.

There is no difference between the manurial requirements of an early and a late crop. Both require the same food, and the late crop being the larger, wants the most food. Yet in actual practice it is found absolutely necessary to use far more manure for the early than for the late crop. The explanation is this—all our common horticultural plants take up their nitrogen in the form of nitric acid or nitrates. No matter how much nitrogen the soil or the manure may contain it becomes available for plant food only after it has been converted by nitrification into nitrates.

Farmyard manure, with its slow nitrifying properties, will furnish nitrates for the later crops, but for early crops some easily soluble nitrogenous manure, such as guano, nitrate of soda, or ammonia salts will be found of great advantage. These substances must not be regarded as substitutes for other manures but only as valuable additions. Nitrates produce the whole of their useful effects only when the soil to which they are applied contains a sufficient proportion, and in a properly assimilable condition, of the mineral constituents required by the plant. If, therefore, the object of the gardener is to grow maximum crops he must in some way furnish his plants with nitrates. If he uses guano, dried blood, fish, bones, stable manure, night soil, or manures of any other kind, the nitrogen contained in these substances must first be converted into nitrates before the plants can assimilate it.

One of the best and cheapest forms in which nitrates can be supplied to the soil is in nitrate of soda. When this manure is used in the garden it is sometimes desirable to apply it in solution. The quantity of nitrate that can safely be used in a gallon of water depends very much on the amount of moisture in the soil. If the soil is saturated with water it does not matter how strong the solution is, provided the proper quantity of nitrate, which may range from one to three hundredweight per acre of ground, is used. The drier the soil the weaker should be the solution. A teaspoonful of nitrate, or one half ounce to two gallons of water, may safely be employed in the garden or greenhouse. The dark colour of the leaves will indicate when the plants have had enough.

The advantages to the horticulturist of the uses of nitrates may thus be summarised : (1) Nitrate of soda serves directly as food for plants ; not having to undergo any change in the soil, it acts more rapidly than any nitrogenous manure of organic origin, such as farmyard or stable dung, guano, blood, fish, rape cake, &c., as the action of these is dependent on their undergoing nitrification. (2) The rapidity with which the nitrate is absorbed by plants, quickly puts them into a state which by the vigour of their development they can the better resist disease, insect attack, and parasitic growths. (3) In seasons following a severe winter, or for early productions of vegetables, nitrate supplied in the spring repairs the lateness caused by climatic disadvantages. (4) Young plants take up nitrates so rapidly, and send their roots into the soil so quickly, that the nitrates cannot escape them, even if washed down by heavy rains.

Harpenden. J. J. WILLIS.

A FAMOUS VINE.

It matters not in which way you look, there is at Harewood more than sufficient to please the eye and interest the mind of those who are concerned with gardening and appreciate beautiful scenery. The stately mansion is one of the finest examples of Corinthian architecture in this country, and the landscape in which it forms so conspicuous an object is of surpassing beauty. The history of Harewood was so admirably told, and the more important features so fully described by Mr. Gordon in the special supplement issued with the GARDENERS' MAGAZINE of April 25, 1896, that I need not refer to the domain generally in giving a few particulars of the famous Muscat of Alexandria vine.

The old Muscat vine at Harewood was planted in the year 1783, and the house enlarged in 1839, according to the inscription on a stone which is built into the back wall of the vinery. The structure is sixty feet long, twenty feet wide, and seventeen feet high at the back. It is what one might term a rather large old-fashioned lean-to house. It is heated with four five-inch pipes, and two four-inch mains which run through to heat some houses beyond. The roots of this vine occupy a border twenty-seven feet wide and the same length as the house. The stem of the plant, which is twenty-seven inches in circumference, enters the vinery near the middle, then branches right and left, and from these leaders (which extend the whole length) canes are trained up to the apex. Formerly the vine was trained on three wires under and parallel with the rafters. This meant great bundles of wood and foliage in one place instead of being interspersed all over the roof. These wires have been supplemented by others running from end to end of the vinery in the ordinary way, consequently both wood and fruit ripen better in the autumn. When the change was made the roots claimed attention as well as the branches, it being evident that something was at fault that was not due to the close training on the roof. The young canes that were run up on temporary wires placed under the sashes ripened indifferently in 1893, which, as we all know, was a grand season. I then decided on having the border and drainage renewed. A good drain was placed along the extreme south side of the border, with junctions by which drains could be connected as the border was being renewed, which has been done in portions in early autumn. Lifting the roots intact out of the old soil was a tedious affair. Those found among the old drainage were quite dead, and were removed, but the live ones were carefully laid aside and covered with damp mats until placed in the fresh compost, which consisted of good fresh loam with plenty of old lime rubble, broken bricks, at the rate of one cartload to three of soil. Plenty of active fibrous roots are now to be found not very far from the surface of the border, and they absorb great quantities of water during the summer months. When the border is moist, liquid manure is applied.

For the last two seasons the vine has borne excellent fruit, many of the bunches turning the scales at one and a half pounds, beautifully finished, and no shanking to be seen. It is a grand keeper, and the fruit, whether on the vine or bottled, keeps plump and fresh till February. The wood of the vine annually increases in strength, and promises well to carry a good crop of fruit next season. In 1897 it carried a heavy and otherwise excellent crop, and over six hundred and fifty were cut out before thinning took place, which goes to prove that it is a free bearer. For the purpose of indicating the high quality of the fruit which the vine produces since its renovation, and not for self-glorification, I would mention that with three bunches cut from it I was successful in obtaining the premier award at the Leeds Chrysanthemum Show in 1896. As this patriarchal and productive grape vine is so great a favourite here, and affords so much interest to visitors, we hope it may long continue to supply the table of its noble owner with richly flavoured fruit.

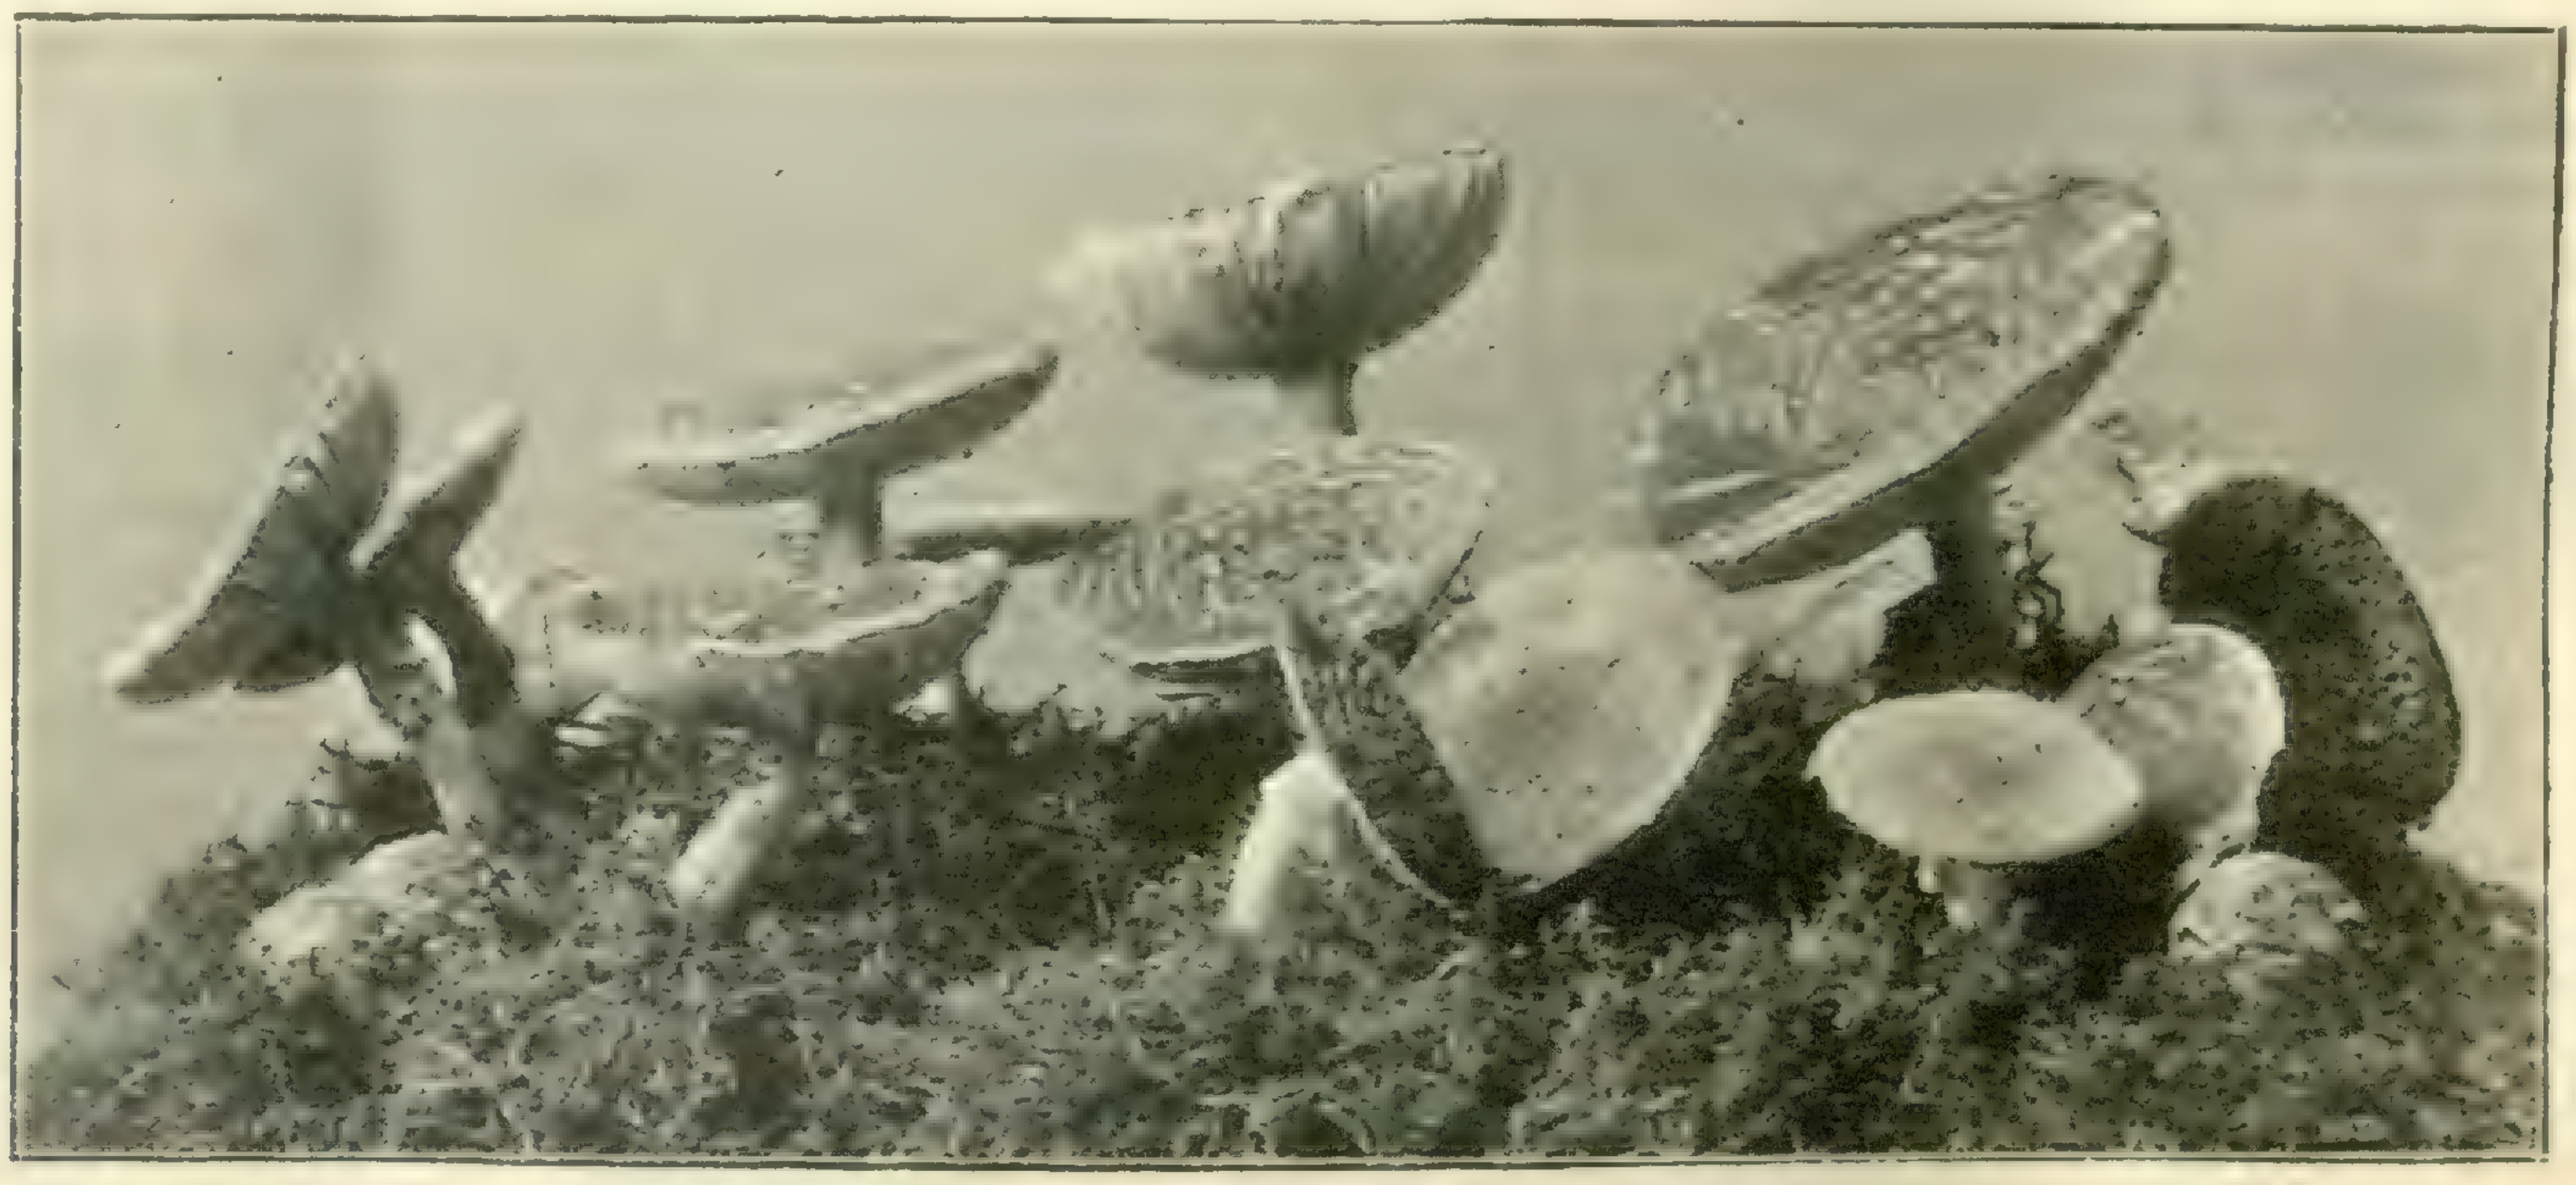
They can also be had of any respectable Seedsman or Ironmonger in the United Kingdom.

The Fly Agaric.

One of the most beautiful of our native fungi is undoubtedly the Fly Agaric, known as Amanita muscarius and Agaricus mascarius, amanita being a sub-genus of agaricus. This species is fairly common throughout the country, and very frequently may be found in beech woods, where its bright crimson pileus is most attractive in the autumn sunlight that passes through the beech foliage. While it is one of the most handsome of agarics, it is also one of the most poisonous, and not a few deaths have occurred through persons eating it. Yet, curiously enough, this fungus is eaten in many parts of Russia without serious results. Of course cooking has a great deal to do with this, but no doubt also, fungi being more largely consumed there than here, the people become in some measure proof against ill-effects or death as a result of eating them, whereas others would succumb. Methods of cooking are, however, the chief cause of preventing ill-effects, and it is the practice to use salt and vinegar in considerable quantities with the water in which this fungus is soaked previous to half an hour's boiling. When there is any question as to the poisonous properties of fungi, it should be remembered that those with a crimson or red pileus, and those that quickly turn blue when broken or bruised, should be always avoided. In no case should the Fly Agaric be eaten.

The Fly Agaric dried and powdered was formerly much used as a fly poison, and this led to the popular name and specific title. The accompanying illustration is from a photograph sent us by Miss M. E. Barron, High Street, Wimbledon, who writes: "The splendid Fly Mushroom grows abundantly under the fir trees and between the bracken on Wimbledon Common, Surrey. The large cap is sometimes six inches across, and of a brilliant pink or crimson colour, beset with angular whitish warts. The head is set on a tall, well-proportioned stalk, and when at its best the species is very conspicuous even at a distance, and it is impossible not to admire it."



THE FLY AGARIC. (*Amanita muscarius.*) *From a Photograph by Russell and Sons.*

A Hobby for Ladies.

In the autumn or late summer, when the various termini of the metropolis are crowded with the returning tourist, male and female, who have been revelling in the rural delights of our coast or inland resorts, the observant eye cannot fail to be struck by the enormous number of ferns which, in baskets and bundles, figure among the impedimenta, and mainly of those of the ladies. On inquiry, we shall find that the bulk of these are the self-acquired spoils of so-called fern-hunting expeditions, while the rest will be simple purchases from hawkers who have saved them the trouble. To such an extent, indeed, does this admiration extend that every popular resort is surrounded by a large area of greater or less barrenness induced by constant up-rooting of the ferns so soon as they declare themselves, so that it is only where, as in the western counties of Devon, Dorset, Somerset, &c., the air is simply laden with the spores, and plants grow so freely and plentifully as to induce a sort of surfeit, that they manage to hold their own at all near the "haunts of men" and women. Now, the pity of it is that in ninety-nine cases out of a hundred this admiration simply means destruction, and thousands of lovely plants which, in their native habitat, were things of beauty and joys for ever—for the longevity of a fern is an undetermined quantity—are rooted up by their admirers only to stand a long course of misusage during the remainder of the holiday, under which they become ragged remnants of exhausted vitality, and lose every vestige of their native charm. Then, if they have survived and reach town, they are probably stuck into the soil in some utterly unsuitable position, and finally find their grave in the rubbish heap the next time a "tidying up" takes place, and the vegetable kingdom is by so much the poorer. Let us now see what would happen if a proper fern hobby were in question, *i.e.*, one in which an admiration for the plants was accompanied by an intelligent appreciation of their needs and peculiarities, and a knowledge of how to bring out the best that is in them. In such a case, if a specimen plant be found worthy of transfer to the home collection, a good double handful of thoroughly damp moss would first be sought for, never a long quest where ferns are plentiful; the fern would then be carefully dug out with as many roots as possible, and these wrapped up well in the moss so as to form a ball, a stout sheet of stiff paper, or double newspaper, is then laid on the ground, and the ball and carefully adjusted fronds rolled up tightly in it, the whole being tied with string. In this way, with a little water occasionally poured in to keep the moss wet, a specimen will stand for two or three weeks without loss of vigour; and when eventually installed, either in a pot in a cool greenhouse or in good compost in a shady sheltered nook in the garden, will speedily establish itself, and well repay the extra care with additional beauty. Curiously enough, though it is by no means rare to see plants of the common Hartstongue in windows, we have never seen but one in which the full capacity was developed. That was a revelation. The plant stood in a north window, and must have been many years old. The pot was twelve or fourteen inches in diameter, and from this radiated all around some thirty or forty fronds, each about two feet long, the whole forming an immense rosette, which quite filled the window. The pot was pitched at an angle so as to give the plant all the light possible, and the fronds were beautifully clean. Evidently it was regularly watered and looked after, and, as a result, one of the weeds of our ferny districts held its own as a splendid foliage plant, instead of being represented, as it usually is, by three or four misshapen fronds without any beauty whatever.

In our capacity of fern specialist, or "maniac," we have frequently burdened our visitors with spare seedlings as souvenirs; but, alas! they seldom serve that purpose long, yet we have ever a vivid recollection of a splendidly tasselled Hartstongue given thus and long forgotten, which confronted us once in a Kentish cottage, with a perfectly dense mass of really marvellous cristation, a foot across and more, as the outcome of our gift and careful culture, and it is precisely here where the lady's hobby comes in which forms our text.

Ferns lend themselves so peculiarly well to outdoor culture, and when tended with loving and appreciative care so well repay it, that a proper study of their capabilities for room decoration cannot fail to handsomely reward any lady who cares to undertake it. How many, for instance, know the extraordinary fact that there are actually in existence several thousand distinct and beautiful varieties of British ferns; more varieties, indeed, than exist of all exotic ferns put together. Add to this that they are all (with two exceptions) perfectly hardy, so that they will survive the hardest winter frost, and, given a few simple rules, are of easiest possible culture, and the wonder ever grows on those who know that not one room in ten thousand boasts even a specimen. Years ago we rigged up two or three shelves in a bay window facing north, and installed thereon a score or so of good varieties; the passers-by were constantly stopping to admire, and a neighbouring nurseryman became quite an enthusiast, while to me they were a perennial source of pleasure. As we have said, the observance of a few simple rules is all that is needed to ensure success. One rule is, "Plenty of daylight, but little or no sun;" another, "Plenty of water, but no stagnation;" a third, "Keep the pots turned one way, *i.e.*, so that the plant faces the window."

Windows facing north or north-east are consequently best, and, given these aspects, nothing but glass should come between the plants and the light. The watering should be attended to regularly, and although in rooms saucers are requisite to catch the surplusage, these should be emptied unless a smaller inverted saucer be placed within them which supports the pots well above the water surface. If the pots be extra well-drained with crocks, &c., this is a very good way and the capillary attraction lessens risk of drought. The position of the pots is important. Many ladies who grow plants in living rooms are constantly turning them round to show their best faces to the room, but in this they are fighting against Nature. As a plant grows, every leaf adjusts itself precisely at the best angle to catch the light; fern fronds do the same. If, therefore, the pots be fixed, the plant grows as it would in Nature, arranging itself symmetrically towards the light. Give it a half turn during this process and the immature growing portions twist themselves round to remedy matters, hardening as they progress. Hence, after a few such twists and turns, the whole plant is more or less askew, and incurably so, since as the fronds mature they lose their power of adaptation. Of course, in the evening no harm is done by a *volte face*, but the risk of their being forgotten is great. The best plan is to mark the front or back of the pots, to aid in its proper replacement when moved. A good open soil is needed, a compost of loam, leaf-mould, and silver sand being suitable for most ferns, in the proportions of two, two, and one, but for ladies it is generally best to obtain what is needed from a nursery.

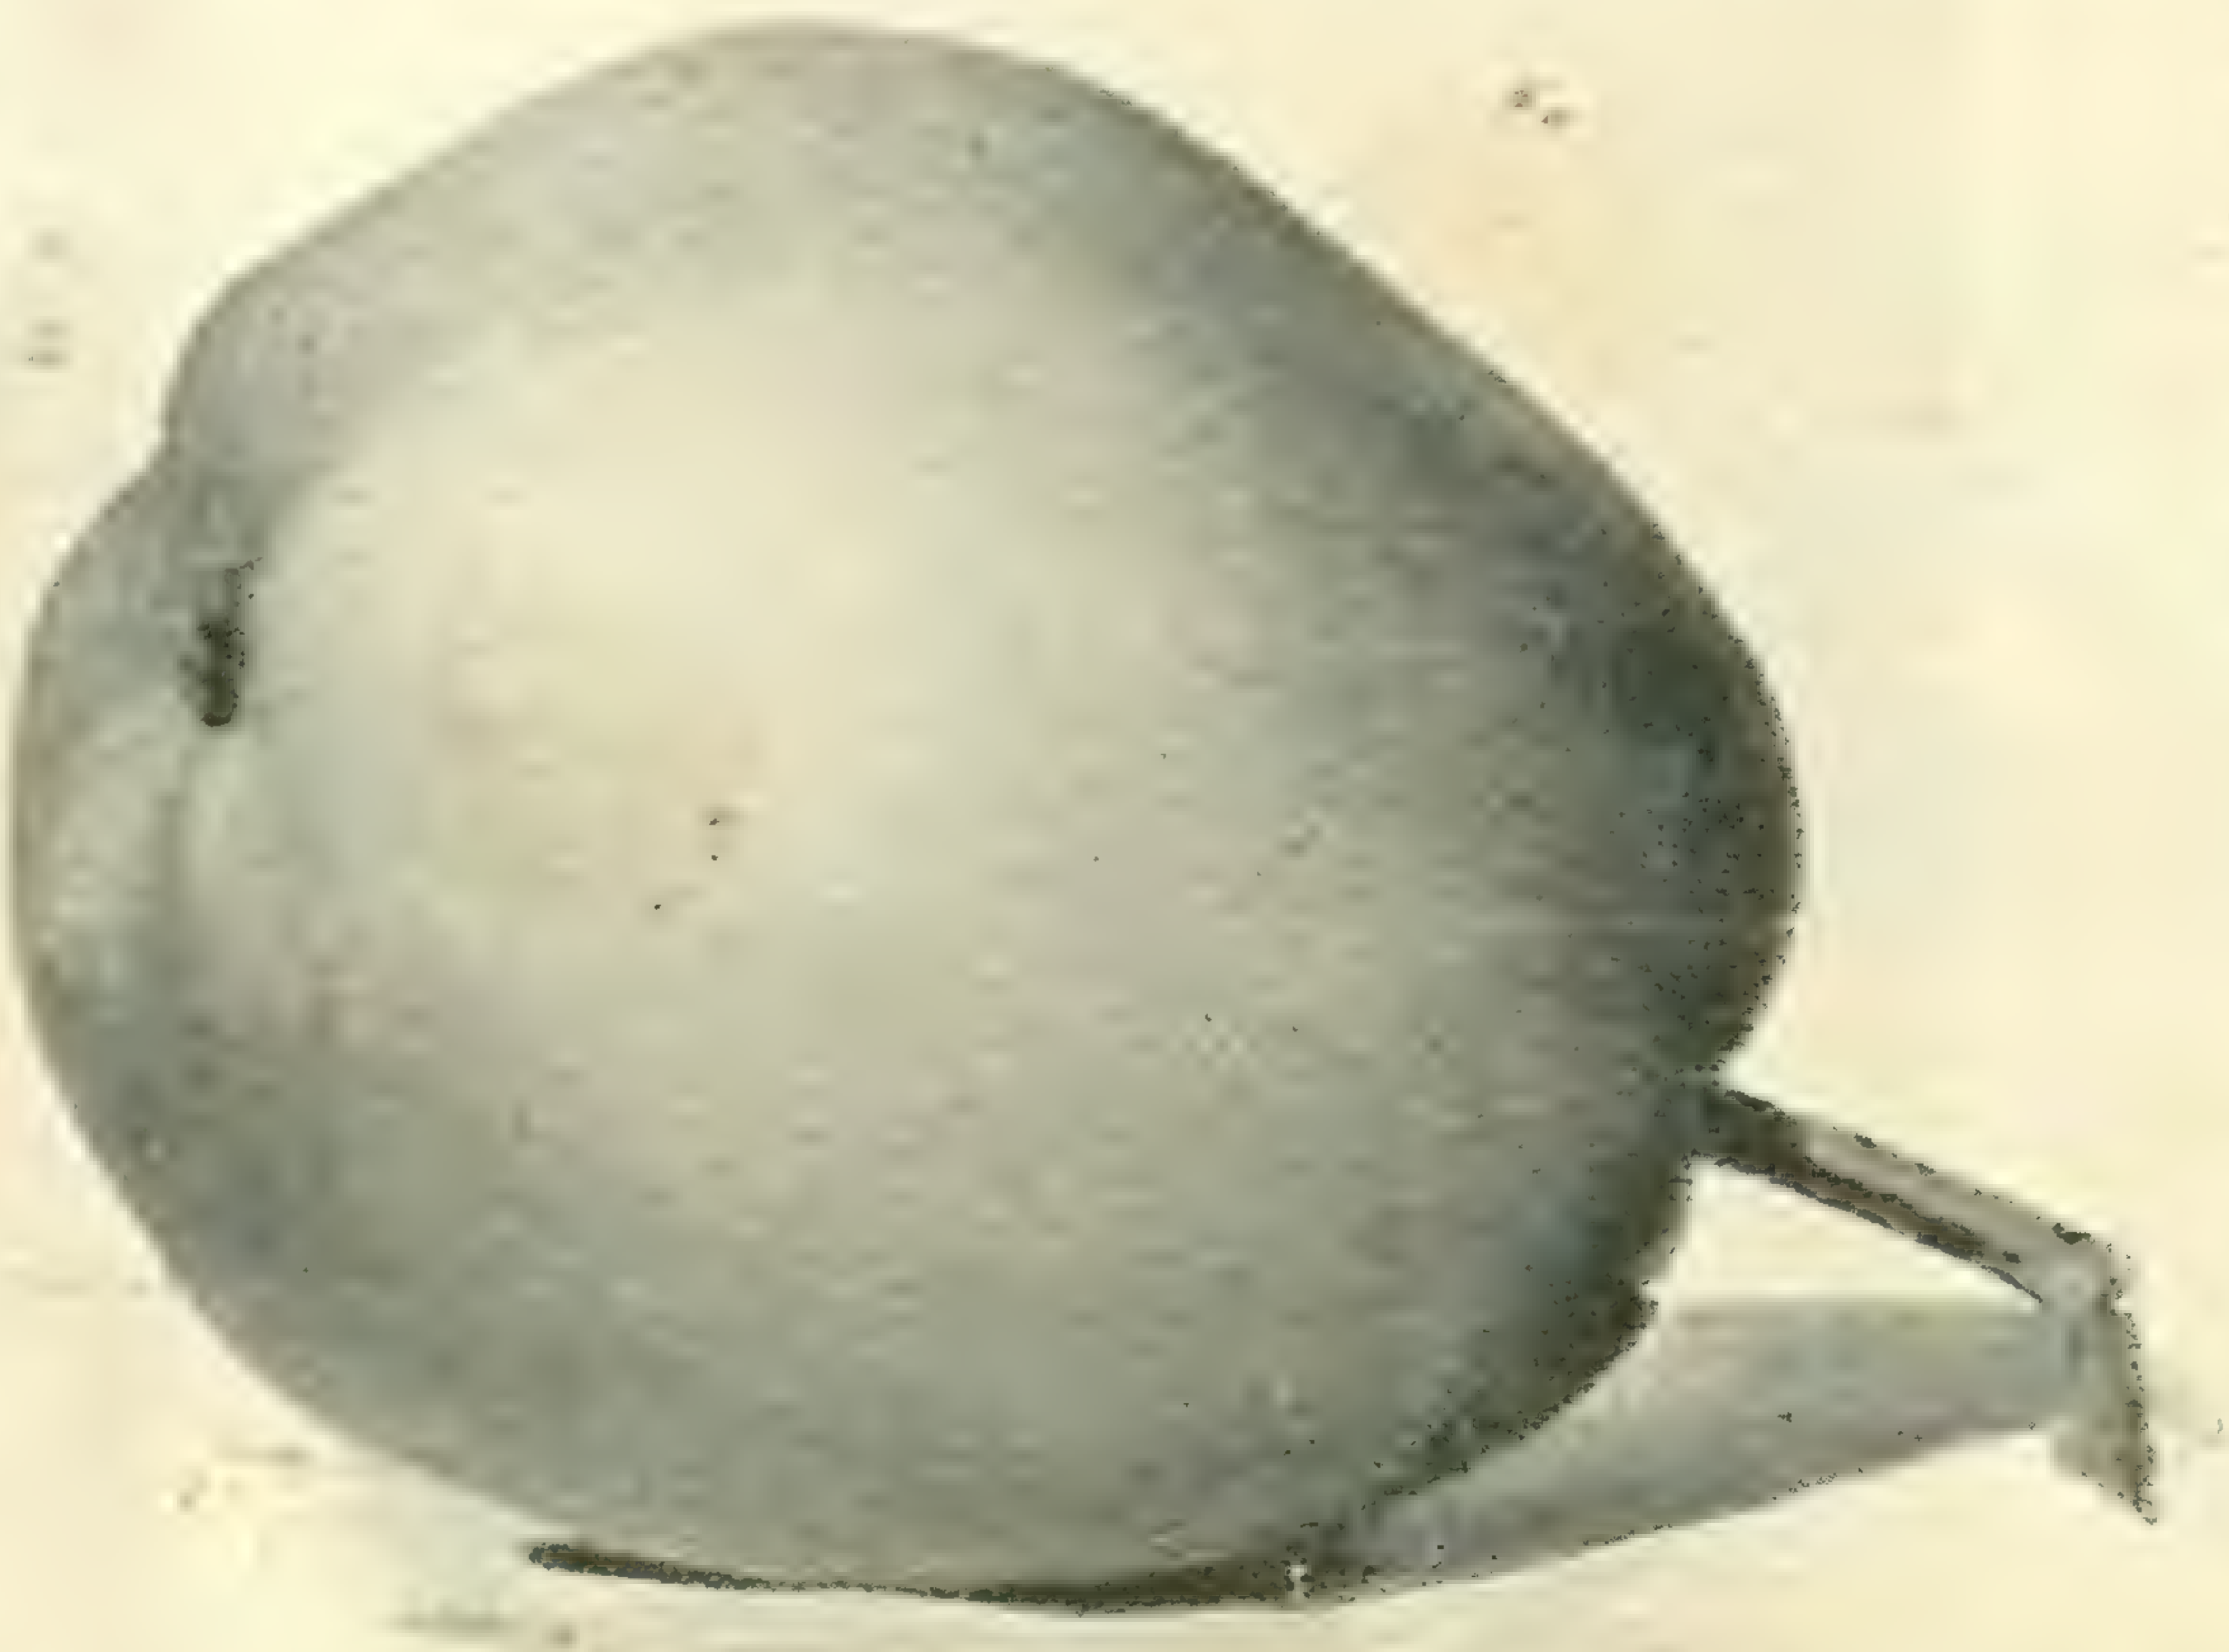
C. T. Druery, F.L.S.

PEAR JEAN DE WITTE.

VARIETIES of pears that are in season at the present, or even a later date, are of immense value, as has been proved not only by market prices, but by the discussion anent late pears that has recently taken place in our columns. One pear has been generally appreciated and recommended for its lateness combined with fine flavour and fairly good appearance. This is Jean de Witte. Mr. Prinsep considers this fine old pear is not thought so much of nowadays, since all the rage has been for huge fruits, but if flavour is to count for anything it should have a place in every garden. Mr. Turton, of Maiden Erleigh Gardens, never fails to recommend Jean de Witte as a good late pear, while Mr. W. H. Lees, of Trent Park Gardens, becomes quite enthusiastic when discoursing upon its merits. A few days ago Mr. Lees sent us a few examples of this delicious pear, one of which we now have the pleasure of illustrating. These were grown on the quince stock, and were of medium size, with handsome, yellowish, russet-speckled skins, clear and bright; they were both attractive and highly flavoured. Mr. Lees grows this pear against a warm wall and allows the fruit to hang as long as possible before being gathered, and by this treatment it is in season from January well into March. Mr. Prinsep asserts that if grown on the pear stock, the fruits of Jean de Witte keep longer in prime condition than if produced on the quince stock. If trees on each of these stocks were grown, it is probable that good fruit would be available in many gardens, even later than the month of March. It has, however, been conclusively proved that this once popular pear has been somewhat neglected of late years, but it is still one of the very best late varieties, and as such should be more often found in gardens.

HYBRID DENDROBIUMS.

FEW subjects, at this season of the year, possess greater interest to orchid enthusiasts than hybrid dendrobiums. Ten or twelve years ago the work of hybridisation was, comparatively speaking, then in its infancy, as only about fourteen or fifteen artificially raised hybrids had flowered or had been described. But the large field then offered by the genus Dendrobium for the operations of the hybridists, has been by them taken up with so much skill and perseverance, that at the present time their labours are frequently and abundantly demonstrated at many of our horticultural exhibitions, and in almost every orchid collection of importance.



PEAR JEAN DE WITTE.

There are now a large number of dendrobiums that have been brought into existence by the hand of the hybridist, and with regard to the plants so raised it becomes a matter of some surprise when we contemplate the great number of distinct species there are in the genus, that there is so little variability in the formation of the flowers, the principal characteristics being in the mixed colouring in the blooms, first brought on by crossing the species together, afterwards by crossing the hybrids with the species, and *vice versa*. Up to the present time nearly one hundred distinct hybrids have thus been obtained. In the production of these the well-known D. nobile and its varieties have been used either as a pollen or seed bearing parent no less than forty times. D. aureum has served, either directly or indirectly, in the raising of at least thirty-five hybrids, and without doubt both species have participated in the parentage of most of the finest hybrids yet raised. It is interesting to note that so long ago as 1866 or 1867 these two species were selected for hybridisation by Mr. Mitchell, then gardener to Dr. Ainsworth, of Manchester, who, after carefully attending to the requirements of the young seedlings for seven or eight years, was amply repaid for his labours when the first seedling flowered. It was named, in compliment to his employer, D. Ainsworthii, the new hybrid partaking of the character of both its parents, and in point of floriferousness superior to either. Subsequently the beautiful and distinct D. splendidissimum grandiflorum was raised by Mr. Seden from the same cross, but he probably having used finer varieties obtained a hybrid with larger and better-coloured flowers. There are other intermediate forms, raised from the same parentage by different operators, so varying in size, and having more or less colour in the blooms that it is difficult to distinguish them sufficiently to know where to draw the line to divide one from the other.

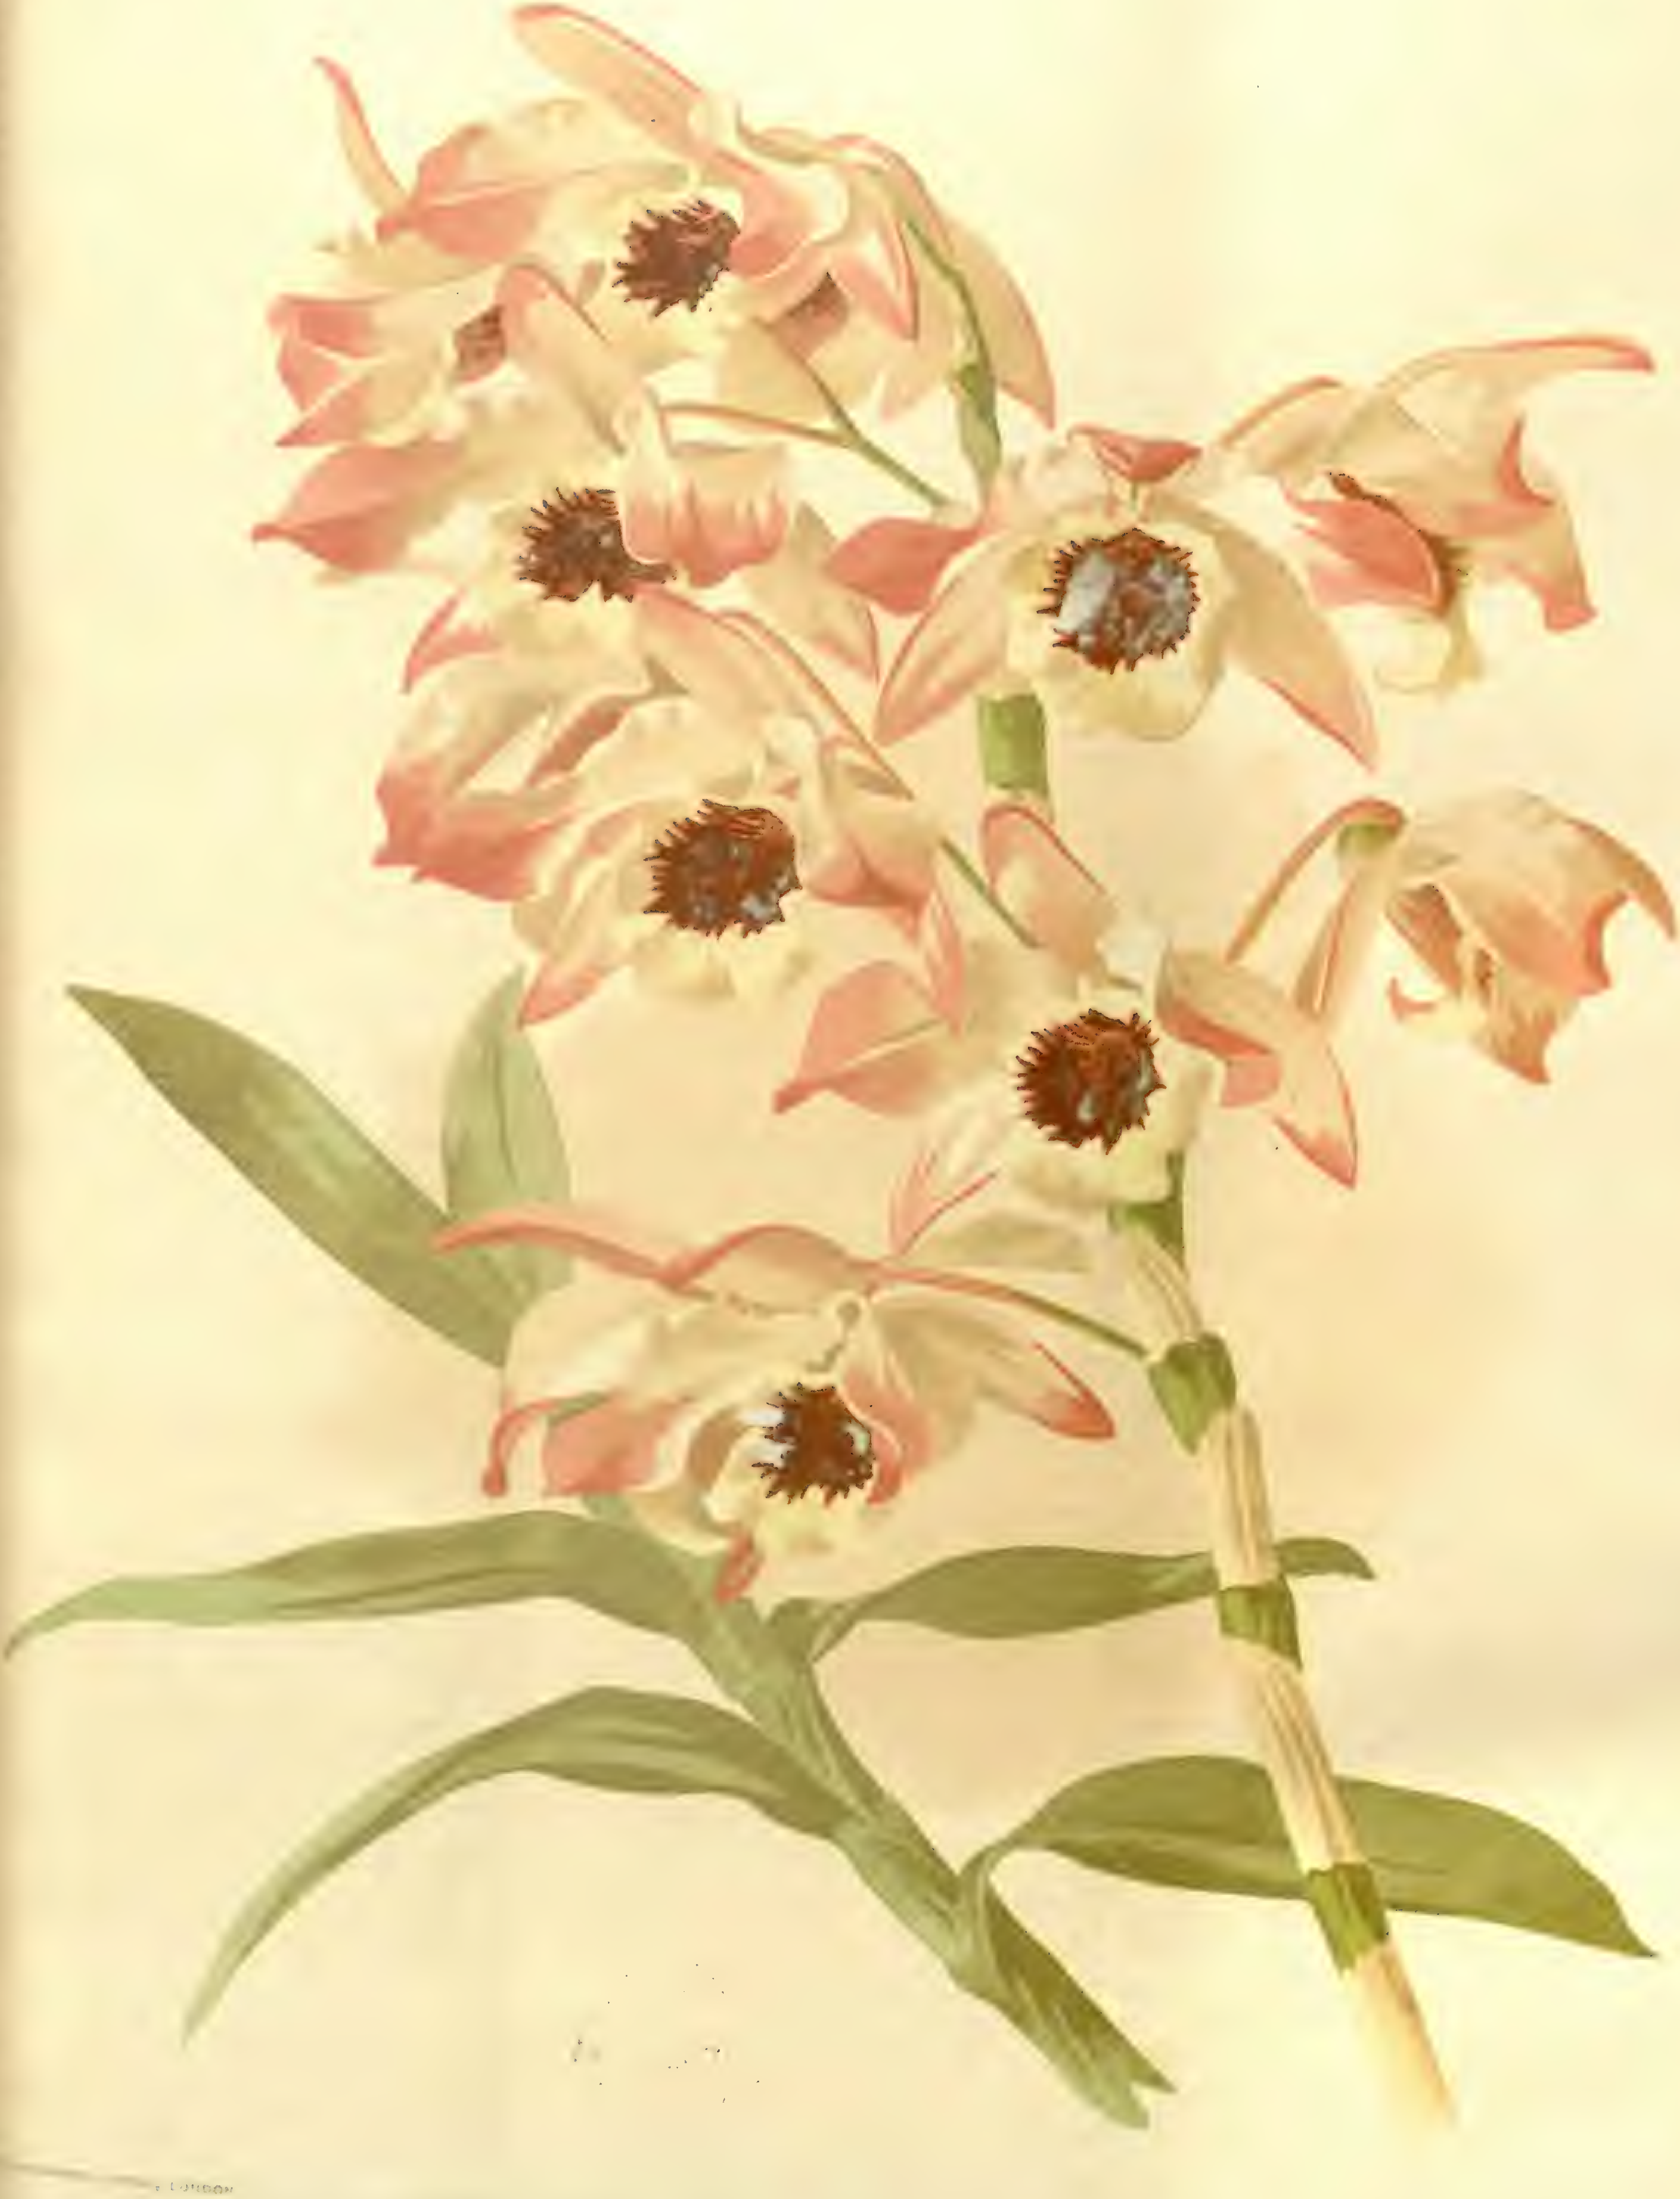
Since 1874, when D. Ainsworthi first flowered, as previously mentioned, numerous other hybrids have appeared, and generally it has been found that almost all the crosses are extremely variable, and from this fact it is no easy matter to discriminate between some of the resulting forms; therefore, intending purchasers would do well to buy hybrid dendrobes in flower only, as probably through no fault of the vendors, they might purchase the same plant under different names over and over again. Dendrobium Dominianum is a very pretty hybrid, also raised from D. nobile, the other parent being D. Linawianum (moniliforme). This was undoubtedly the first hybrid in the genus, having been raised by the gentleman whose name it bears several years before D. Ainsworthi appeared. D. Ainsworthi and its congeneric hybrids have not only proved valuable acquisitions to the dendrobium family, but hybridists have found them extremely useful for crossing purposes. This may be inferred from the fact that out of the numerous hybrids raised, in which hybrids themselves have participated in one way or the other D. Ainsworthi has shared in the production of quite five-eighths of these. Amongst these may be mentioned the beautiful D. Apollo grandiflorum and D. Rubens grandiflorum, both raised by Mr. Cypher, also D. chrysodiscus, D. melanodiscus, D. Clio, D. Dellense, D. Doris, D. euryalus, D. Andromeda, &c., &c., which were obtained by various other operators. Of the remaining hybrids which have participated in raising new seedlings D. Cassiope, D. euosmum leucopterum, and D. endocharis form the principal. D. Findleyanum has proved itself useful for hybridising purposes, having either, as a seed or pollen parent, produced over a dozen new varieties. The small white-flowered D. japonicum has been the means of giving us such lovely hybrids as D. Virginia, D. Doris, D. Æneas, D. Vannerianum, D. striatum, D. Wardiano-japonicum, and D. endocharis. The two last-named varieties are well worth adding to any collection, principally on account of the delicious fragrance of their flowers.

It is singular to note that the popular Dendrobium Wardianum as a seed-bearing parent has hitherto produced but few progeny, the beautiful D. micans being one of the best raised from it, and which, doubtless, it will be difficult to surpass. On the other hand, D. Wardianum as a pollen parent has been more successful, producing such hybrids as D. Alcippe, D. Bryan, D. Aspasia, D. euterpe, D. Findleyano-Wardianum, D. Clio, and D. Wardiano-aureum. Although the well-known D. crassinode has been in cultivation since 1868, only one hybrid has been recorded, Mr. Cookson having been successful in obtaining a cross between that species and D. luteolum. The progeny is named D. Astræa. It may be well to mention here that D. crassinode, while in its native habitat, shared with D. Wardianum in the production of the rare D. crassinode-Wardianum. Several fine hybrids have been derived from D. Falconeri, the best of them being the splendid D. Venus = Falconeri × nobile. The following well-known species have shared in the production of a single new hybrid each—D. MacCarthæ, D. Pierardi, D. Parishi, D. bigibbum, D. signatum, D. crystallinum, D. albo-sanguineum, D. sanguinolentum, and D. primulinum. Of the tall-growing section of dendrobes D. Dalhouseianum is, up to the present time the only species from which hybrids have been obtained. Thus, the pretty D. porphyrogastrum was raised between D. Huttoni × D. Dalhouseianum. D. striatum was derived from D. japonicum × Dalhouseianum, D. illustre, between D. chrysotoxum × Dalhouseianum and D. strætius from D. Linawianum × D. Dalhouseianum Each of these hybrids are extremely interesting, because of the widely different characteristics of the parents used. Perhaps the most remarkable feature connected with these hybrids is the advent of D. chrysotoxum as a parent, and of its being the first of the evergreen section which has participated in the production of hybrid dendrobes. These four D. Dalhouseianum hybrids were raised in the establishment of Messrs. James Veitch and Sons of Chelsea, by their foreman, Mr. Seden, to whose skill we are indebted for a great many other beautiful dendrobium hybrids. Up to the present time only one hybrid has been derived from the Australian species, and that between D. Kingianum × D. speciosum, which was raised by the late Mr Spyers in Sir Trevor Lawrence's collection at Burford. So far as we know at present no success has been obtained in raising hybrids from the nigro-hirsute section of dendrobiums. Including these and the strong, tall-growing species, and those of the evergreen section, there still remains a large and interesting field open for workers in this particular branch of horticulture, and what the future may produce it would be difficult to predict; but, without doubt, many difficulties and disappointments will have to be overcome before the muling of the whole dendrobium family is successfully accomplished. The beautiful hybrid which forms the subject of the accompanying coloured plate is in Baron Schröder's collection of Mr. Ballantine's most recent successes.

Burford Lodge Gardens. W. H. WHITE.

The Paris International Exhibition, to be held in 1900, was referred to in our issue of February 19. We have to add to our former remarks that the Royal Commission for the Exhibition has appointed the following [illegible] as a sectional sub-committee for "agriculture, food, horticulture, forestry, fisheries, and wild crops": Earl Spencer (chairman), Earl of Crewe, Duke of Fife, Earl of Dudley, Earl of Jersey, General Sir Redvers Buller, V.C., Sir Horace Plunkett, M.P., Sir Edward Grey, M.P., Sir Trevor Lawrence, Bart., [illegible] George Russell, Sir Jacob Wilson, Mr. W. T. Thistleton Dyer, Mr. [illegible] Grattan, and Mr. Paul J. Madden.

Supplement to
THE GARDENERS' MAGAZINE.
March 5, 1898.



LONDON

DENDROBIUM SCHRÖDERIANUM.

RHODODENDRON PRÆCOX.

HARDY shrubs flowering during the month of February are so few in number that they should be widely known and taken full advantage of in any alterations that may be made with a view to enhance the attractions of the garden early in the year. More especially does it appear desirable that the beautiful Rhododendron præcox should be more fully utilised in garden decoration than has yet been the case, for in seasons that are at all favourable to outdoor vegetation it commences to bloom early in February, and produces a bright glow of colour extending over several weeks. This precocious rhododendron is of hybrid origin, and was raised some years since at Ormskirk from a cross effected between R. ciliatum, a Himalayan species with rosy white flowers, and R. dahuricum, a Siberian species producing flowers of a rich rose-purple hue. The growth is neat, and the bright rose-lilac flowers are produced with remarkable freedom, and although not possessing the warmth of colour for which some of the later-flowered forms are remarkable, they are decidedly attractive. R. præcox is plentiful in nurseries to which special attention is given to hardy trees and shrubs, and the other day we saw a fine mass in the Waltham Cross Nurseries. Our illustration represents a superb bank near King William's Temple in the Royal Gardens, Kew, which presented a highly attractive appearance throughout the past month, and proved to demonstration the value of the precocious rhododendron in the production of winter effects.

BANK OF RHODODENDRON PRÆCOX IN THE ROYAL GARDENS, KEW.

CHOICE DAFFODILS.

IN the Sheffield district the usual time for daffodils to flower is about the third week in April. This season, however, the varieties have advanced swiftly, and to indicate the mildness of the season, I may state that the lovely miniature daffodil Narcissus minimus expanded its first flower on January 16. We have it planted in a pocket, on the southern slopes of a rockery, and certainly this neat little gem is well worthy a sunny nook, in the most select collection. Other early and small flowering kinds are N. cyclamineus, N. major, N. nanus, and N. juncifolius, the latter a rush-leafed species and producing one of the smallest flowers of any. N. triandrus albus, perhaps better known as Angels' Tears, has been often used in cross-fertilisation owing to its great beauty. It likes to be planted on a sunny slope with plenty of sand round about its bulbs. These fine daffodils can be purchased at very little cost, and when in flower they are most attractive and sweet.

The following is a selection of the best daffodils in cultivation at the present day, beginning with the trumpet varieties first, such as Captain Nelson and Countess of Desmond, the latter with soft primrose perianth and yellow trumpet. Then we have that gorgeous variety Glory of Leyden, with its larger expanded trumpet and broad yellow perianth; this, however, is a mid-season variety. Golden Spur, Henry Irving, Her Majesty, and Hudibras are other choice forms, together with that most distinct form J. G. Baker, which has a rich primrose trumpet and is rather dwarf. John Nelson has a larger uniform bloom of a somewhat drooping habit. Johnstoni Queen of Spain is most elegant, and for vases it is invaluable, as it is of a soft delicate yellow with reflexing perianth, while at the mouth of the trumpet some blooms are spreading and others straight.. N. maximus is a finer yellow, and very telling in a collection of cut-blooms, arranged in glasses; this is fond of good rich soil, but dislikes crude manure. Continuing, we have Mrs. H. J. Elwes, Shirley Hibberd, and P. R. Barr, the last two are very distinct. Sir William Harcourt and Obvallaris (Tenby daffodil) must not be omitted, nor the two imperial forms, Emperor and Empress, both raised by the late Mr. Backhouse, of Darlington. Horsfieldi is another fine thing, very closely resembling the latter, but has the advantage of coming into bloom a little earlier. Bicolor grande is not to be despised, for it has a cool constitution, and coming in late, it is useful. J. B. M. Camm forms a very good companion to the last, and it is one of the most distinct varieties, the colour being a pleasing shade of pale chrome yellow in the trumpet, and white perianth. Madame Plemp has a larger flower, and one of finer substance. T. A. Dorrien-Smith is a very good variety, with the perianth a little shorter than the trumpet, the colour is pale sulphur. Colleen Bawn, Matson Vincent, and Mrs. Thompson are early, and followed by Mrs. J. B. M. Camm, a most elegant form, with white periath and sulphur trumpet; the flowers are pendulous. Mrs. Vincent is of rare beauty and perfect form. All these white and pale sulphur varieties thrive much better in virgin loam than elsewhere, provided plenty of sand is mixed with it. Avoid manure for them, as their constitution is weak, and they soon die if not treated as they like. Madame de Graaff is a most lovely form, and one of the best whites in cultivation; it has a large and well-formed flower, without any trace of coarseness. The last of the Ajax varieties to be mentioned is that gigantic form Weardale Perfection. This is one of the largest, combined with splendid habit and flowers of great substance, the segments being very large and of a creamy white shade; the immense trumpet is primrose-yellow. Weardale is rather late in flowering, and is altogether a very choice daffodil.

In the medium and short cupped section there are some very pleasing daffodils, with colours ranging from yellow to deep orange-scarlet. The flowers are most valuable when cut and arranged with a little of their own foliage in glasses, as they are light and elegant. N. Barri conspicuus and N. Barri Sensation are two very good varieties, followed by Gloria Mundi, a fine bold deep red flower, and a form having a good constitution. Queen Sophia and the giant Welsh daffodil, Sir Watkin—the largest of the Incomparabilis group—make, with the more recent introduction, Lulworth, with its pure white perianth and bright orange-red cup, a famous trio. Siddington was introduced about the same time as the last mentioned, and it is a free-flowering variety, usually producing twin-flowered scapes. Duchess of Westminster, belonging to the Leedsi group, is like a six-pointed star; Katherine Spurrell has a broad and overlapping perianth, and should have a select place in the smallest collection; Gem is another acquisition to this beautiful group, being white and of splendid form.

The Nelsoni group of daffodils is very interesting. N. major and N aurantius, with Mrs. C. J. Backhouse and William Backhouse, make a fine quartette. The first two are heavily stained with orange-scarlet round the expanded cup. As these all flower so late they seem to be even more attractive than some of their earlier relations. In conclusion, I hope this interesting family will be more cultivated in future, especially among those who have time and inclination to hybridise and cross-fertilise them, so that the forms may still continue to increase, and our gardens enriched.

Totley Hall Gardens. T. W. BIRKINSHAW.

APPLES IN HAMPSHIRE.

It cannot be said that this part of the county is famous for its good apple orchards; in fact, this particular neighbourhood is, I fear, somewhat noted for the reverse. In the Havant district, and from there on to the borders of Sussex, apple growing is a great feature. Orchards there assume large dimensions. Fifty acres are under culture by one grower, and successfully cultivated too. The varieties are numerous, of the best kind, and thoroughly suited to the soil, and the market requirements also. Much of the fruit finds its way into the Portsmouth market, where it has a ready sale at fairly good prices. In this neighbourhood the great fault planters have made in the past has been the selection of unsuitable varieties. In but few orchards are to be found really deserving varieties; too much faith has been placed in local varieties, such sorts as Hambledon Deux Ans being a great favourite. In this immediate locality apple culture might be successfully carried out, both soil and climate being quite suitable. For years past I have endeavoured to impress upon planters the advantage of growing good varieties only, and procuring a good class of trees. Too much thought is given to the purchase of cheap trees, simply because they are cheap. This is an error.

In this garden we have under cultivation one hundred and forty varieties. The object in planting so many was to test their suitability for the locality. To a person intending to plant an orchard for profit I strongly advise a limited selection. The point is to find out what is required, and plant accordingly. It is useless in this part to grow late-keeping varieties. English-grown apples cannot compete with American or Tasmanian produce. Even varieties like Cox's Orange Pippin, really good in quality, have to give way to the imported fruit in the Southampton market. In spite of what so many persons write, from supposition, English cultivators have to face these facts. So few of the general public, too, know the quality of such apples as Cox's Orange Pippin. To me it is astonishing, too, that small cultivators should be content with local varieties, worth only two shillings per bushel, when their neighbours are obtaining double the amount for superior sorts.

In the face of American and other competition I strongly urge intending planters to so arrange their varieties that all their fruit is cleared six weeks before Christmas. This advice may appear strange to many persons who write advising the planting of late varieties. Storing the fruit does not pay in a general way; you may secure one or two single customers who appreciate the good quality of superior English apples, but in a general way late apples are a failure as far as their market value is concerned. I am too well acquainted with the best fruiterers in the southern ports to advise any other plan. Plant varieties like Worcester Pearmain in quantity, and fear not, for there is always a sale for this apple, it being handsome in appearance and in season at a suitable time. In September and in the early part of October there is a dearth of really good dessert apples. The varieties in existence at the present day do not admit of a succession. After the Quarrendens, Lady Sudeley, Irish Peach, Worcester Pearmain, and Nanny or Sussex apples as they are termed, there are none of any moment, until King of Pippins, Cox's Orange, Blenheim Pippin, and Ribston Pippins are ready. The cry is for more dessert kinds; pudding apples, as the kitchen sorts are termed, are plentiful. An apple which in time will do much to fill the void is Benoni when it becomes better known. In general appearance it much resembles King of Pippins, but ripens fully a month earlier, and is perhaps of better quality. It is certainly a pleasing apple in every way. The habit of growth, too, is desirable, being upright in character, vigorous and and yet a free bearer. I am much impressed with this apple after an extended trial. As yet, though, it seems to be little known outside of the nursery or large garden. So much are the fruiterers driven into a corner to procure dessert apples in October and the latter part of September that they readily buy up Cox's Orange Pippin and the King of Pippins. I am aware there are other varieties than those named ripening at the period quoted, but they are much too small for the best class of trade. Duchess of Gloucester, Golden Pippin, and a few others ripen then, but all are useless for the above reason.

In the autumn of 1890 my employer decided to plant five acres of grass land as a test of the value of apple culture, and with the object of finding employment for labour The site was sheltered from the east, south, and south-west winds by fir trees, not too near to interfere with the growth of the apple trees. In a situation like this, at an altitude of three hundred and ninety-five feet above sea level, where strong south-westerly winds prevail at the end of August and the first fortnight in September, as well as cold biting easterly winds in April and May, shelter is absolutely essential to success. The average rainfall is thirty inches; last year this quantity was exceeded by one and a half inches, whereas the previous two years we were several inches short of the average quantity. Abundant sunlight, coupled with the necessary soil constituents, enables the fruit to colour perfectly. In fact, with few exceptions, apples do not colour better anywhere.

As the trees here under my charge have succeeded, and equalled expectations in growth and productiveness, a few remarks as to the method of culture pursued, and selection of varieties, may be useful to others. The selection of varieties and the kind of tree is important. With the object of obtaining early fruit of both kitchen and dessert kinds, the selection was made accordingly. With the large number of two thousand trees it must not be inferred that no mistakes in selection were made. The chronicling of failures often leads to success afterwards in gardening matters. I will depart from the usual rule, and commence with the failures. In making the selection I was persuaded to plant Ecklinville Seedling largely, it being one of the best market apples. Knowing it to grow freely and crop well, I planted two hundred and fifty trees. Experience now compels me to say in this part it is the worst market apple possible. The skin being soft, as well as the flesh under it, it is easily bruised, and therefore valueless. Dealing first with kitchen v I planted freely of Lord Grosvenor, which, as is generally is a close imitation of Lord Suffield although not quite so It, however, has the merit of resisting canker in this soil, which case with Lord Suffield. Lord Grosvenor grows freely and bears heavy crops of fruit, the first of which are ready by the middle of A Warner's King is really a grand apple where space can be given it allow of a free extension of its branches, thus bringing it earlier bearing than though it had to be somewhat severely pruned to restric its limit of growth. Good specimens of this apple always command highest price. Lane's Prince Albert was largely planted also, inde was a happy choice, as the habit of growth is desirable in a limited sp As a cropper it is too well known to require praise from me. Pomona I planted but a dozen trees; the number ought to have b times that number, as it possesses ail the characteristics of a g market apple. Of the Queen I planted a dozen, which was really twelve too many; as a market apple it is too flat and dull in appearance to be appreciated. Mère de Ménage here succeeds admirably, colouring almost too deeply to be sought after. As a rule it is not a heavy cropper here it is quite so. Bramley's Seedling succeeds really well in the but being a late variety it is useless for the market, but is valuable home consumption.

Other desirable varieties, but planted sparingly, and those for purposes, are Alfriston, with which I am well pleased, for at the end January the fruit was in splendid condition. Waltham Abbey Seedling I cannot recommend, as, in spite of severe root pruning, it grows much too freely and produces fruit much too sparingly. Tower of Glamis is good, and so is D. T. Fish, which for ordinary purposes may very well be called Warner's King. Dumelow's Seedling, strange to say, is not a success; although the trees are healthy and bear freely the fruits are of poor quality. Yorkshire Greening annually bears a heavy crop of full-sized fruit, which, however, are not of a taking appearance. Golden Spire is a desirable variety to plant, but Keswick Codlin is not. Stirling Castle requires too much attention in the way of manuring to obtain a sufficiently vigorous growth to command success. For this reason I do not recommend it, although many persons like it.

Amongst dessert apples, Devonshire Quarrenden is the first inquired after; it crops freely, but does not make vigorous growth in this soil. Irish Peach I do not advise; the fruit is too small, soft, and generally unsuited. Red Astrachan would probably meet with more success. Worcester Pearmain, as previously stated, is a complete success. If I had planted no other sort I should now have no cause for regret. King Pippins is good, and always meets with a ready sale. Cox's Orange Pipp and Blenheim Pippin are too well known to need comment, except to too many trees cannot be planted. Growers must be content to wait least ten years before the latter does itself justice; after that, if it succeeds, it is perhaps the most regular cropping apple we have Henniker, if we could induce it to bear rather more freely, would deserving of more space, as it finds a ready sale. The crop is, howe too sparse to warrant its inclusion to a large degree. Royal Russet can recommend. Pineapple Russet is far too soft in its flesh to be of much service. Sturmer Pippin is too late and too dull in appearance be desirable. Benoni I previously alluded to in favourable terms.

The kind of trees to plant is important. I am not so deeply impressed with the value of the Paradise stock as some persons are. The point they claim is that of coming early into fruiting condition. In our soil I prefer trees grafted on the free stock or seedling apple, as they are more likely to grow vigorously. As to their not cropping so early, experience leads me to say such an assertion is unfounded, as with the trees would bear the season after planting if it were necessary or advisable to allow them to do so. There is a freedom of growth about seedling stocks not obtainable in the Paradise.

The time to plant apple trees is an important point in their welfare. I prefer the early autumn, directly the leaves change and while the soil has still some warmth left in it. If planting cann done before the end of November I prefer to wait until the first wee March, and would rather plant then than not at all, or even wait the following autumn. From March to November newly-planted if kept moist about the roots with the aid of a thick mulch of half manure, must produce much fibre, and surely they are in a better the following spring than newly-planted trees.

Swanmore Park Gardens. E. MOLYNE

Chiswick Gardens.—Although Dr. Ince regards the gardens at Ch as a white elephant to the R.H.S., his opinions on such a matter are of no c quence whatever. To one Fellow holding such an opinion, there are a hundr least of horticultural capacity who think differently. We would all like to see money spent on the gardens, not only to erect needful and proper trial houses, also furnishing more of labour. But there can be no doubt whatever but that trials at Chiswick have the greatest interest and value to the community. It may be said that the trade utilises them not, nor respects the results. That may be but these trials are conducted in the interests of horticulture generally, and for benefit of the Fellows. Whatever of scientific teaching may be engrafted on gardens, practical horticulture must dominate.—A. D.

The Parentage of Roses.—In my contribution to the GAR MAGAZINE on this subject, La Boule d'Or has, by a clerical error on my been unfortunately substituted for Bouquet d'Or as one of the finest derivations from Gloire de Dijon. I take the earliest opportunity of making correction. I also may say that Ulrich Brunner, though of German name, be accurately described as having been of Teutonic extraction, having derived, I understand, from that enormously large, but not very refined, entitled Paul Neyron. I generally find that varieties which are especially able by reason of their dimensions are somewhat lacking in beauty of form. roses which approximate most closely to perfection are very rarely of im size. There are, nevertheless, a few exhibition varieties which may be re conspicuous exceptions to this general rule.—DAVID R. WILLIAMSON.

THE POSITION OF SCOTTISH HORTICULTURE.

In reviewing the position and progress of horticulture in Scotland during the past twenty years, one is almost amazed at the changes that have taken place in connection with some of the most famous gardens of former times, and at the large number of once well-known gardeners that have passed away; men who, in their time, so worthily filled their respective situations and did so much towards raising the art and science of horticulture to the high position it has now attained.

In regard to the changes in the fortunes of many estates, the depreciation in the value of land has been one of the most important factors, and circumstances over which neither owner nor employé could control have necessitated severe reductions to be made in the staff of workmen and a strict curtailment of expenses in connection with the garden wherever possible. From this cause many of the most historic places of a quarter of a century ago are now but a shadow of their former greatness. The ownership has in many cases been changed, or the mansion and surroundings have passed into the possession of others for the time being, and where this arrangement is made for a series of years the results are generally satisfactory, and the introduction of wealth from this source has prevented many estates from being reduced to the lowest extremities.

These changes, however, have not always proved to the advantage of the gardener, who probably has spent the greater and best part of his life in one situation, and has made the special tastes and requirements of one family his own interest and study, and who realizes late in life that he must start afresh, in accordance with new ways and ideas, a proceeding often found to be easier in theory than in practice; for the preference so frequently manifested in modern times for a younger man, may lead to the enforced retirement from the sphere of duties to which he has devoted life-long labours, at a much earlier period than he anticipated, or probably was prepared for. Against this somewhat dark side of present-time horticulture may be placed the fact, that a great number of gardens have in late years been established throughout the country by the wealthy merchant classes, especially in the neighbourhood of the large centres of population and industry. These places have, to a great extent, provided useful and lucrative employment, for much of the surplus labour and talent set free in rural districts; and although many years must pass before they can favourably compare for sylvan beauty and historic association with older places, yet it is to these modern gardens that one must turn to find in quantity the rare and costly orchids, and other plants, that have of late been introduced, and being housed in structures built upon the most improved principles, combined with the best and most skilful cultivation that experience and wealth can devise, renders them the subjects of the glowing accounts so frequently brought to the notice of the readers of horticultural readers.

The events already referred to have also been instrumental in changing the methods of furnishing and decorating, both under glass and in the open. Of the former, the large specimen plants once so popular have given way to those of quicker growth that are suitable for the decoration of rooms, or that supply cut flowers in quantity for that purpose; while the immense numbers of tender plants that were formerly used for the embellishment of the flower beds in summer are now replaced where possible by those of a hardier and more useful and lasting character, among which carnations, roses, chrysanthemums, and the hardy herbaceous plants are the most popular. These do not produce such a display of colour for a brief period as did the ordinary bedding plants, but the balance is in their favour of requiring but a comparatively slight amount of attention to grow them well, and the flowering season of one or other of the species extends over the greater part of the year, while as cut flowers for vase decoration they are most useful either for home use or for sending to a distance.

The last sentence brings forward a point that has influenced the position of the northern gardener considerably, viz., the parcels post, and cheaper railway rates for horticultural produce. A few years ago the period known as the London season was looked upon as the most leisured time, so far as requirements from the garden were concerned, and any important alterations or improvements were then carried out, with the full assurance that nothing would occur to interrupt the speedy accomplishment of the work, as the occasional hamper of produce on special entertainments was the only requirement for some three or four months. At present, however, it is seldom that a day passes without a request for some favourite flowers, grasses, or evergreens to be sent by post, while lower rates and more rapid transit enables fruit and vegetable gathered late in the afternoon, and travelling several hundreds of miles through the night, to be delivered in London the following morning in time for placing upon the breakfast table, and in condition almost as fresh as though grown in the home connties.

While these events have occurred in connection with the professional gardener, they have also exercised considerable influence upon the large and ever-increasing company of amateur cultivators, to whom is due the honour of having made the greater progress of any in recent years. In this the weekly circulation of horticultural literature, and seed catalogues containing full descriptions of many flowers and vegetables, and much cultural information, that are now so freely distributed among all classes, have done much to awaken and sustain the interest in all matters relating to horticulture that is so apparent at present. A few years ago the amateur was tolerated at exhibitions, mainly owing to his subscription, and his exhibits were often relegated to the most obscure part of the exhibition tent, as though unworthy of a more prominent position. Time, skill, and application have changed this, and it is not unusual at present to encounter a little group of professionals eagerly discussing the merits of the produce staged by their less fortunate, though seldom less modest neighbours; and in certain classes as vegetables, hardy and half-hardy plants and flowers the comparison is frequently not unfavourable to the amateur.

The extended culture of hardy fruit for market is making fair progress in country districts, especially with strawberries and bush fruit, which meet with a ready sale, both for private use and the requirements of the preserve manufacturer. The same cannot as yet be stated in respect to apples, pears, and plums, though in districts very favourable to the growth of these, extensive plantations have been made; but, generally, the planting is confined to gardens and small orchards.

The excellent articles that have appeared in the pages of the Gardeners' Magazine under the title of "Wasted Orchards" have certainly been the means of stimulating an inquiring spirit among the proper class to benefit thereby, and this may in course of time develop a better knowledge and system of fruit culture being carried out than exists at the present time.

Brief reference may be made to some of the annual exhibitions held in Scotland, and of these the autumn meeting of the Royal Caledonian Horticultural Society, which is held in the Waverley Market, Edinburgh, is the most representative and popular, and it forms the yearly concentrating point for gardeners from all parts of the kingdom. It is needless to enlarge upon the convenience and suitability of the Waverley Market for holding a great show, or to the efficient management that has for many years endeavoured so successfully to keep the exhibitions well abreast of the times by adding new features by way of substantial prizes for various classes of produce whenever necessary.

The Scottish Horticultural Association, which was instituted twenty years ago, has done good service for the advancement of horticulture in many directions, and it was under the auspices of this association that the now famous chrysanthemum exhibition is carried on. Started about twelve years ago in a very modest way, it soon showed signs of outgrowing the accommodation provided for it, and it was soon afterwards transferred to the Waverley Market, a proceeding that gave rise to considerable doubt as to whether it would be possible to furnish the huge structure in an effective manner in the month of November.

At that time it was mainly a chrysanthemum show, but, to fill space and add variety to the concern, several gardeners, among whom was myself, were invited in 1887 to forward collections of hardy fruits for this purpose. The appeal was well responded to, and a very representative display was the result. The following year the society offered prizes, and some specials by nurserymen were also offered for collections of apples and pears, and vegetable classes were instituted. These have been augmented from time to time, until now the society has one of the finest winter fruit shows in the kingdom, and those who saw the fine display of grapes and other hothouse fruit which were staged last November, as well as the quantities of hardy fruit and vegetables which are always well shown at Edinburgh, must have been amply rewarded, apart from the grand blooms of chrysanthemums that were staged in such perfection and quantity, which, together with the many special exhibits, filled the spacious market to overflowing.

Galloway House, Wigtownshire. JAMES DAY.

The Mole.—Whether the mole is injurious or not from a cultivator's point of view is a question upon which, probably, there will be always some difference of opinion. Many maintain that mole-hills are not only very unsightly, but that they prevent the mowing grass from being properly cut. They overlook the fact that if the hillocks were knocked about in the spring, and the fine soil of which they are composed were spread over the surface, they would have an excellent and inexpensive top-dressing for their fields. Another recommendation lies in the system of surface drainage which is effected by the mole's "runs"; while a third, and perhaps the most important, consideration is the fact that the mole preys not only upon earthworms and field slugs, but also upon the larvæ of many coleopterous and dipterous insects which are very destructive to the roots of grasses and other field crops. The late Mr. Henry Reeks of Thruxton, near Andover, who was a practical farmer as well as a good naturalist, was strongly in favour of sparing the moles upon agricultural land. If the natural enemies of the mole were not destroyed, there would be much less need for trapping their velvet-coated prey. Weasels kill moles—as long ago remarked by Gilbert White in his fortieth letter to Thomas Pennant—so do owls when they can catch them above ground on summer nights; so do buzzards The common buzzard is a capital mole-catcher, and in the vicinity of mole-hills will take up a position on some low bough of a tree, from which it will glide and seize a mole the moment the earth moves on its approach to the surface. In this way (*i.e.*, by watching and jumping down) buzzards destroy not only moles, but numbers of rats and mice. But the weasel, the owl, and the buzzard are thoughtlessly trapped, poisoned, or shot, on the score of their interference with game, the result being that the farms are overrun with rats, mice and moles, and the farmers in self-defence have to pay for their destruction instead of leaving them to the supervision of "nature's police." It becomes, then, a matter for consideration how best to get rid of moles on land where, for the reasons above stated, they have unduly increased. Macgillivray states that every mole appropriates to itself a particular tract of ground, in which it forms a kind of fortress under a hillock, but this we are not able to confirm. On the contrary, it is certain that many use the same "runs" in common, just as rats and mice do. This is made evident from the fact that a mole-catcher will trap mole after mole in the same "run" to the number of a dozen or more, resetting his trap time after time nearly in the same spot. To discover which are the most frequented "runs," the plan is to mark every fresh mole-hill by a light pressure of the foot, and to examine it next morning to see if a mole has passed by and partly obliterated the depression by fresh upheaval. In two or three days it will be seen what part of the ground is most used, and there the traps may be set. Although iron traps may give less trouble to set, the kind of mole-trap most in vogue is the old-fashioned wooden one—a semicylinder of wood, with grooved rings at each end in which are fixed horsehair nooses kept in position by a peg in the centre and strained by a cord attached above ground to a pliant stick bent downwards. As the mole passes through one of the nooses and moves the peg aside. the pliant wand springs up, and the mole is held tightly in the noose.—F. E. Harting, in *Board of Agriculture Journal.*

FLOWERS FOR EASTER.

EVERY season has its special favourites in particular flowers, but perhaps at no other season of the year do they enter more generally into our national life and religious rites than at Easter, and certainly at no other time do they bring with them a greater pleasure of hope and joy.

The last few years have witnessed a great addition to the demand for cut flowers and plants for this festival in town and country alike ; for now scarcely a city cathedral or parish church is found without its plants and flowers on Easter Day, and, consequently, the demand on the gardener's resources is at this time somewhat severe, and coming as it does at a time when other work of all kinds is most pressing, the tax is all the more felt ; but thanks to the gradual introduction of coloured flowers for this festival, the demand is not so difficult to meet as it otherwise would be. One cannot help being struck with the variety as well as the quantity of flowers now used, as compared with former years, for this festival, for whereas white and red were the only colours thought desirable to use at one time, we now see various colours introduced in combination, and with striking effect. And this same change, by the way, is gradually taking place in regard to wreaths and floral tributes of all kinds for funerals, for here, too, up to a short time ago, white only was thought admissible, and but very seldom was anything else seen ; but now it is no exaggeration to say all colours and shades are used, with pleasing results to the eye, and certainly with an enhanced general effect. Still, the demand for white flowers continues to be great for all festive occasions, and with but little prospect of their becoming less so for Easter as time goes on.

Foremost and favourite of all Easter flowers comes Lilium longifolium Harrisi, and the undisputed sway this has held for the past twelve or fourteen years seems likely to continue, for the ease with which it can be brought into flower for Easter by procuring early imported bulbs, and the readiness with which it lends itself for all manner of decoration, has caused it to become a general favourite.

The practice here has been to procure bulbs immediately they are imported and pot at once, then placing them in cold frames with a slight covering of leafmould or ashes, and as soon as the growths begin to show about an inch in length we remove the covering, and gradually bring on in a greenhouse temperature. Their greatest enemy is greenfly, and if this is allowed to secure a lodgment on the young growths but for a short time only irreparable damage is done, and deformed flowers, with yellow, sickly growth, will be the result. To prevent this slight fumigations of an approved insecticide should be given about every ten days, and for all decorative purposes the pollen should be carefully removed as soon as the blooms are sufficiently expanded to permit this ; and if the blooms are too early for any purpose they are required for, they may be considerably retarded by cutting the spike on the first bloom expanding, and placing in a dark, dry cellar or room ; and pot plants may be similarly treated, and will thus keep much longer than if left in the heat and sunshine to expand, and still retain their waxen freshness.

Next to Lilium Harrissi for Easter decorations comes the old favourite Richardia æthiopica, and for general usefulness will hold its place for some time to come ; notwithstanding the more recent introduction of the two beautiful yellows, Elliottiana and Pentlandi, used in a cut state, as we sometimes see, the spathes have an air of stiffness, but when used with a little of their own green bold foliage, the leaves form a perfect set off to these striking spathes. The Madonna lily, or Lilium candidum, is not so extensively grown for Easter as at one time. Still, it deserves a place where room can be spared, and its sweet delicate fragrance will always make it acceptable ; but it will not, however, stand the amount of forcing that L. Harrissi will, and those requiring it for Easter will need to procure very early bulbs and bring them on from the first very steadily—doubtless this drawback accounts for its not being grown in such large quantities as it used to be.

Among azaleas there are many that may be named, but Deutsch Perle is the most useful of all the whites, and one that will the most readily respond to gentle forcing, and where a quantity of white flowers are in demand this must be regarded as being indispensable. And among the Amœna type there are several varieties well worthy of growing for their usefulness for all decorative puroses, and for the pleasing bits of colour they afford when arranged with other subjects, and when allowed to grow without any attempt at keeping them to a particular shape they have an easy grace about them we miss in the other varieties. A useful addition to this class is one named obtusa, the flowers are of a darker crimson than any of the others known to me of this class. Spiræas japonica and astilboides do not meet with the same amount of favour in private places they at one time did, especially is this so with the former species. The strong disagreeable smell the flowers have very largely detracts from their value, but where there is a large demand for groups they will always be found useful for forming a groundwork for other subjects. Spiræa confusa, on the other hand, is much sought after ; and either for forcing or general decorative work, or for the front of the shrubbery borders, its graceful clusters of pure white flowers have made it a valuable addition to our spring flowering plants.

Prunus sinensis flore pleno is an excellent plant for decorations, and being of a nice bushy habit of growth, with great freedom of flowering, should secure a place for early forcing. Prunus triloba is another useful subject for pot culture ; it is a much stronger grower than the above, and perhaps not quite so free in flowering or early, but its soft rosy-pink flowers, either by themselves or in association, have a very pleasing effect. Cerasus Watereri forms a valuable addition to this class of plant, and when better known will be more generally grown both for forcing and for shrubberies. The adaptability of this handsome cherry for flowering under glass early in the year is admirably shown in the excellent illustration of the Winter Garden at Frogmore given in the Christmas number of the GARDENERS' MAGAZINE, published in December last.

Among lilacs Charles the Tenth and Virginalis are the two best singles in their respective colours for forcing, and with the [illegible] ported plants, specially prepared, there is no difficulty in having a [illegible] supply of this much-appreciated flower. It is a good practice to [illegible] quarter specially devoted to these plants, where they can be plant[illegible] after forcing, and allowed to remain for a year or so; and if a little [illegible] is taken in pruning them over very nice bushes can be obtain[illegible] second and third year from forcing, which will give a plentiful [illegible] flower about Easter time, and amply repay for the attention given. [illegible] are several promising things among the newer double varieties [illegible] class, which a trial may verify.

Closely resembling these, and very useful about this time, is [illegible] plicatum ; not so useful, however, for cut flowers as for corridor or [illegible] house furnishing, but withal very acceptable. Staphylea colch[illegible] also be named as a useful shrub for forcing about this time, and its [illegible] cate white flowers can be utilised in a variety of ways. Camell[illegible] gradually being crowded out of cultivation by other more useful [illegible] profitable plants for furnishing ; in some places they have alr[illegible] disappeared. One must at times express a lingering regard for [illegible] bygone favourites, and hope room will still be kept for a few of the varieties, among which may be named Chandleri elegans, Donckelaari, Lady Hume's Blush, Alba plena, and Reticulata, the last-named an excellent subject for the back wall of a cool house, and a few of its handsome blooms would act as a pleasant reminder of the changes which come over men and things.

Acacias are another class of plants gradually losing ground as pot plants, but which for this time of the year are most useful. A. Drummondi and A. armata may be named as useful for pot culture, while A. dealbata and A. Riceana are two excellent species for planting out the latter makes one of the most graceful plants it is possible to conceive when allowed to spread under and depend from a lofty roof.

The foregoing are but a few of the most useful things for Easter decorations. Space does not permit to mention in detail the roses and lilies of the valley, the hyacinths, and tulips, and daffodils that will be fortcoming in great profusion and endless variety.

Eaton Hall Gardens. F. N. BARNES.

CONIFEROUS TREES AT HOLKHAM.

IN the recently-published transactions of the English Arboricultural Society, the following particulars are given of the fine collection of coniferous trees in [illegible] Fulmodestone Wood on the Holkham estate, the property of the Earl of Leicester. The visit was made by the members of the society on a wet day, [illegible] the writer says, with reference to the inspection of the wood in question : [illegible] we saw what is probably the most magnificent collection of coniferæ in England. Rain was then falling heavily, and the long grass was completely saturated, but the sight of such a succession of noble trees, perfect in shape and form, and some of them throwing out boughs of such length as to make an approach to the [illegible] a somewhat difficult operation, led us to forget any temporary discomfort resulting from the disagreeable weather. The planting of these trees was undertaken merely from love of arboriculture, and not with any idea of reaping profit. The wood is two hundred and eleven acres in extent, and is well drained, and [illegible] coniferæ are protected by a pre-existing crop of larch and other timber [illegible] which have been felled from time to time to promote their growth with[illegible] reducing their protection. Planting has been going on gradually ever since 1[illegible] when the earliest of the coniferæ were placed here. Some that were pla[illegible] not more than twenty-two years ago have reached a good height already, and [illegible] almost every instance the growth has been very rapid. A blown silver fir, [illegible] we saw on entering the wood, was measured, and was computed to contain [illegible] hundred and sixty-two cubic feet of timber. But that is only by way of parenthesis. Pursuing our way through the wood, we came up to two specimens of [illegible] Webbiana, planted in 1851, and one of which has a quarter girth of 18 inches ; [illegible] nobilis, 21 inches, over 70 feet high ; Wellingtonea gigantea, planted in 185[illegible] 26½ inches, over 100 feet high ; Thuja Lobbi, 9 inches, 50 feet high ; do., 15[illegible] inches ; do., 15 inches, 70 feet high ; Picea amabilis, 22½ inches, top broken by wind ; Abies canadensis (Hemlock Spruce), 9 inches ; A. Douglasi (Ame[illegible] Red Fir), 16½ inches, about 80 feet high ; do., 20 inches ; do., 20¼ inches [illegible] planted in 1852) ; A. Albertiana (Californian Hemlock Spruce), 14 in., [illegible] high ; do., 14¼ inches, 90 feet high (both planted in the early "fifties," and [illegible] fine specimens). There is a group of these majestic trees which we named [illegible] "Albert group." A fine avenue of Picea nobilis claims brief attention, and [illegible] an avenue of Abies Douglasi (Rocky Mountain type), planted twenty-two years [illegible] but all the larger trees of this species were planted in 1852, as already sugg[illegible] A close belt of coniferæ on an exposed side of the wood has created some [illegible] culty for Mr. Munro. Formerly it was a sort of copse, which had to be cut [illegible] periodically, and when that was done it left the main part of the wood open [illegible] injury. So the hazel was cleared out, and Picea nobilis, Abies Douglasi, Cupressus Lawsoniana, and others were planted in pretty closely with the [illegible] of giving permanent shelter. Now, however, they have grown so well [illegible] Munro does not wish to part with any of them, and does not know wh[illegible] sacrifice. Some of the Picea nobilis were bought in pots at £5 apiece, [illegible] planted in 1851 or 1852. One of these has at present a quarter girth [illegible] inches, and is 95 feet high. As regards the Abies Douglasi, one of them is [illegible] to have grown up 6 feet 2 inches in two years. The only specimen of [illegible] Lambertiana, the tallest of pines, has a quarter girth of 16¾ inches. [illegible] planted in 1851. This species does not thrive here. Two very beautif[illegible] standing together, and both planted in 1861, engrossed attention for some [illegible] The one is Picea lasiocarpa or Lowi, and the other P. grandis. The [illegible] 17½ inches quarter girth, and 90 feet high ; and the former 18½ inches [illegible] girth, and 80 feet high. Probably the largest nobilis—at least, the largest [illegible] on our tour through the wood—is 26 inches quarter girth, and is about [illegible] high. This was one of the plants bought in pots at £5 each. A Picea p[illegible] measured 11 inches quarter girth, and has a height of 42 feet. Only one [illegible] men of Libocedrus decurrens (sometimes called Thuja gigantea) was obs[illegible] its quarter girth is 14 inches. Amongst the other specimens noted [illegible] Sequoia or Taxodium sempervirens, 14 inches, 65 feet high ; Cupressus [illegible] iana, 15 inches, 75 feet high ; a group of Thuja Lobbi, nearly 90 feet high, [illegible] girth of from 15½ inches to 16 inches ; Cedrus deodara, 11½ inches, [illegible] high ; Thujopsis borealis, a very fine specimen, very graceful and sym[illegible] and Cryptomeria japonica, also very fine. All the underwood hereab[illegible] felled about ten years ago, and the younger coniferæ were planted w[illegible] suitable spot was found.

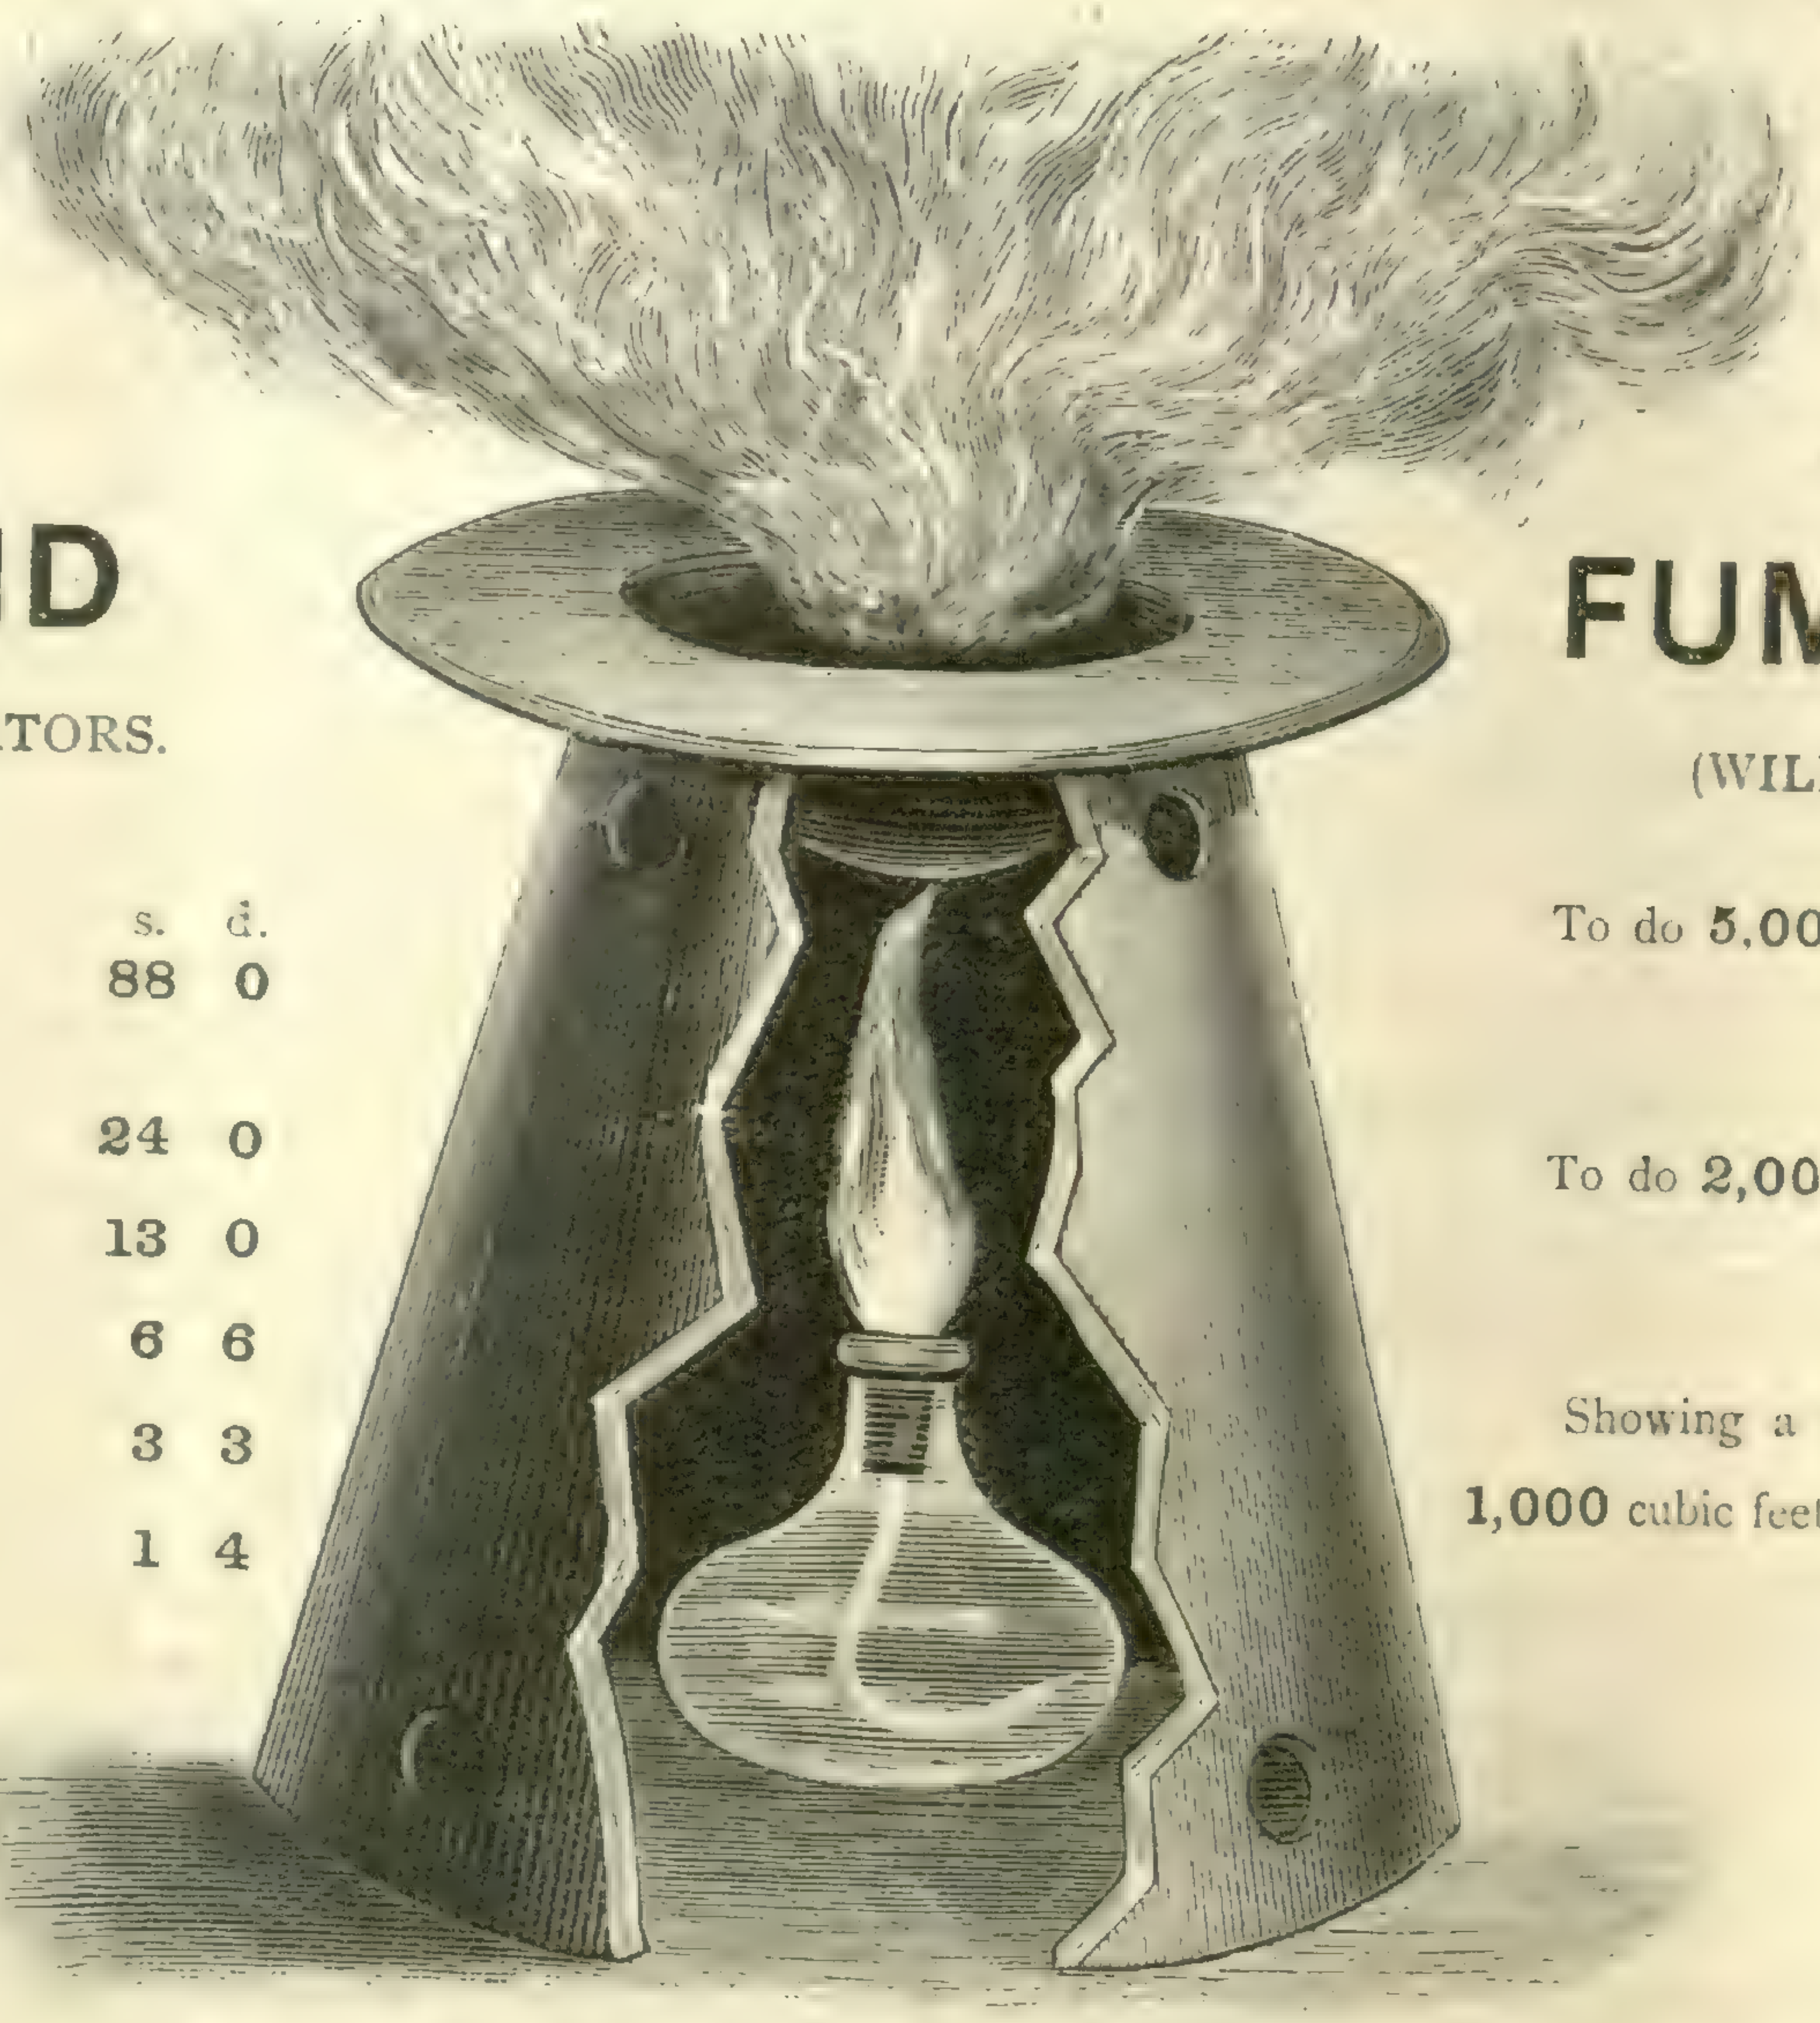
THE XL ALL SPECIALITIES.

THE CHEAPEST, MOST SIMPLE, AND BEST FUMIGATOR IN EXISTENCE.

A LIQUID COMPOUND, SIMPLY EVAPORATED from a SMALL COPPER CUP by the AGENCY of a SPIRIT LAMP.

25 per cent.
stronger than
any other.

VAPORISER
in
the Market



COMPOUND

FOR USING IN THE FUMIGATORS.

	Enough for cubic feet.	s.	d.
½-gal. tin	160,000	88	0
Bottle. No. 1	40,000	24	0
No. 2	20,000	13	0
No. 3	10,000	6	6
No. 4	5,000	3	3
No. 5	2,000	1	4

FUMIGATORS,

(WILL LAST FOR YEARS.)

To do 5,000 cubic feet of space at a time, 2s. each.

To do 2,000 cubic feet of space at a time, 1s. 9d. each.

Showing a cost for fumigating of only 8d per 1,000 cubic feet of space.

RICHARDS' PATENT, NO. 11,297.

XL ALL VAPORISING FUMIGATOR

XL ALL LIQUID INSECTICIDE (*Wash, Patent*)
The most certain in effect, and safest Wash in the market. ½-pint, 1*s.* 2*d.*; 1 pint, 2*s.*; 1 quart, 3*s.* 6*d.*; ½-gallon, 5*s.*; 1 gallon, 10*s.*

XL ALL TOBACCO POWDER
The strongest and finest grade of Powder yet produced. In 6*d.*, 1*s.*, 2*s.* 6*d.*, and 5*s.* tins.

XL ALL MILDEW WASH.
A clear liquid. Kills Mildew and Insects at the same time. Price, 1 gall., 12*s.* 6*d.*; ½-gall., 6*s.* 6*d.*; 1 quart, 4*s.*; 1 pint, 2*s.* 6*d.*

XL ALL LIQUID MANURE.
1 pint, 1*s.*; 1 quart, 1*s.* 6*d.*; 1 gallon, 3*s.* 9*d.*; 4 gallons, 12*s.* Cheaper in bulk. To be used 1 part to 50 of water, making the cheapest Plant Food in the market.

XL ALL PERFECTLY SOLUBLE MANURE.
For Top-dressing and Dissolving in Water. In 1*s.*, 2*s.* 6*d.*, 5*s.*, and 10*s.* tins.

XL ALL GRADUATING MANURE.
For mixing with the soil when repotting or making up new, or renovating old borders. In 1*s.*, 2*s.* 6*d.*, and 5*s.* tins. In bags, ½-cwt., 10*s.* 6*d.*; 1 cwt., 21*s.* In bulk at special rates.

XL ALL SPECIAL TOMATO MANURE.
The latest chemical triumph for the production of abundance of highly-coloured fruit, even in the poorest soil, at the same time imparting to the plants a decided disease-resisting power. Per cwt., 16*s.*

XL ALL WEED DESTROYER.
In Liquid. All details on application.

BARR'S select Vegetable SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH.

A FEW SPECIALITIES FOR 1898.

BARR'S Green Canadian Asparagus.—Remarkable for its fine quality, productiveness, and evenness of growth, with fine pea-green coloured
1-OZ. PACKET, **9**d. ; 2-OZ. PACKET, **1**s. **3**d.

BARR'S Lightning Runner Bean.—A valuable acquisition, bearing in abundance clusters of delicately-flavoured pods ; remarkably early.
PER HALF-PINT, **1**s. **9**d.

BARR'S Monstrous Long-podded Broad Bean.—The earliest, largest, and most productive of Long-podded Broad Beans ; of fine,
PER QUART, **2**s. **6**d.

BARR'S Covent Garden Compact-top Beet.—Medium-sized roots of fine flavour ; highly recommended. PER PACKET, **6**d. ; PER OZ., **1**s. **3**

BARR'S Golden Wax-pod Dwarf Butter Bean.—Remarkably early and productive ; the long fleshy pods require no stringing, and when boiled a great delicacy.
PER PINT, **2**s.

BARR'S Standard Brussels Sprouts.—An exceptionally fine variety, very sturdy, extremely hardy, with abundance of dark green sprouts.
PER PACKET, **1**s. & **1**s. **6**d.

BARR'S "Best of All" Dwarf Autumn Cabbage.—A fine, distinct little Cabbage, remarkably early, dwarf, and of specially fine cooking
One of the best for Spring Sowing. PER OZ., **1**s. **6**d. ; PER PACKET, **6**d.

BARR'S Early Dwarf "Best of All" Cauliflower.—Remarkably early, dwarf and compact ; with heads as white as snow.
PER PACKET, **1**s. **6**d. & **2**s. **6**d.

BARR'S Champion Solid White Celery.—Very solid and sweet, remaining longer in condition than any other White Celery.
PER PACKET, **1**s. & **2**s. **6**d.

BARR'S Pride of the Market Cucumber.—A specially fine variety, dark green and of handsome shape, a fine all-the-year-round Cucumber.
PER PACKET, **1**s. **6**d.

BARR'S Silver Globe Onion.—A grand Exhibition Onion, handsome in form, of large size, mild in flavour, and a good keeper.
PER OZ., **2**s. **6**d ; PER PACKET, **1**s.

BARR'S "First of All" Olive-shaped Radish.—Remarkably early, short-leaved little radishes, coming into use very quickly ; flesh crisp delicate flavour.
Scarlet or *White*, each, PER PINT, **2**s. **6**d. ; PER OZ., **6**d.

BARR'S New Thick-fleshed Tomato.—Surpasses all other Tomatos in depth of fruit, solidity of flesh, high quality, and heavy cropping.
PER PACKET, **1**s.

For a Select List of the Best PEAS for Exhibition and for maintaining a Succession of Green Peas from to November see Barr's Seed Guide, free on application.

Barr's choice Flower Seeds.

A FEW SPECIALITIES FOR 1898.

BARR'S Giant-flowered Antirrhinum.—A new strain with very large and handsome flowers of rich brilliant colours ; height 2 feet.
PER PACKET, **1**s.

BARR'S Long-spurred Columbines.—An extra selected strain, of great beauty. PER PACKET, **2**s. **6**d.

BARR'S Beautiful Single Aster (A. sinensis).—The plant forms a branching bush covered with single flowers 4 inches across, of a lively with golden centre, height 15 inches.
PER PACKET, **2**s. **6**d.

BARR'S magnificent mixture of Balsams.—Of shapely growth, medium height, and beautiful colours. PER PACKET, **1**s. **6**d. & **2**s. **6**

BARR'S Celosia plumosa, mixed.—A beautiful strain of this graceful annual ; the feathery plumes are of the richest colours.
PER PACKET, **6**d. & **1**s.

BARR'S Prize Strain Cineraria.—Comparatively dwarf, flowers large and of brilliant colours. PER PACKET, **2**s. **6**d. & **3**s. **6**d.

BARR'S Selected Strain Coreopsis grandiflora.—One of the finest of border plants, flowers very large and of a *rich deep golden*
PER PACKET, **1**

BARR'S Magnificent Delphiniums.—In very choice mixture. PER PACKET, **1**s. **6**d. & **2**s. **6**d

BARR'S Giant Strain of Digitalis (Foxglove).—Large handsome flowers, the stem ending in a terminal flower of immense size, colours rich height 3 feet.
PER PACKET, **6**d. & **1**s.

BARRS "Tree Lupins."—Saved at our Long Ditton Nurseries from various beautiful delicate shades. PER PACKET, **1**s.

BARR'S Superb Giant Petunia.—The largest flowered of all Petunias and the most beautiful, handsome varied colours.
PER PACKET, **2**s. **6**d. & **3**s. **6**d.

BARR'S "Long Ditton" Highly-coloured Polyanthus.—An extra selected strain. PER PACKET, **2**s. **6**d.

BARR'S "Long Ditton" Highly-coloured Primrose.—An extra selected strain. PER PACKET, **2**s **6**d.

BARR'S choicest mixture of Sweet Peas.—From all the newest and largest-flowered sorts. PER PACKET, **1**s. & **1**s. **6**d.

A full List of the Best Novelties for 1898 will be found in our SEED GUIDE, free on application.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds It is full of Hints, and will be found invaluable to Gardeners, Amateurs and Exhibitors *Sent free on application.*

ALLOTMENTS IN NORTHUMBERLAND.

THE last half-century has seen a remarkable exodus from country districts into towns, where physical, and too often moral, deterioration occurs. Thinkers all over the country lament this state of things, and through the agencies of county councils, &c., are endeavouring to place land within the reach of all who desire it in the neighbourhood of towns and in the country. The Northern Allotment Society at Newcastle-on-Tyne has acquired several estates during the last seven years, altogether over six hundred acres, mostly freehold or copyhold. This society is a public institution of which any person may become a member upon payment of the sum of one shilling per annum; no liability attaches to membership, and the amount merely entitles one to information. Members become advised of any action the society may contemplate, and have the opportunity of joining in it or objecting. The various estates were all brought before the members of the society and applications invited for them. When a quorum of members was formed this little syndicate took up the business with the vendors, and made their own bargain. Having purchased an estate, each one of these quorums or syndicates determined for itself the whole conditions, regulating the division, allotment, and holders of the land. The group in each case laid down new roads necessary for opening out each estate, the fencing, water supply, and other work of a similar character. The cost of improvement is added to the purchase money, and the total amount apportioned over the estate at so much per lot by a competent and independent valuer. If possible, the estate is allotted amongst the purchasers by mutual agreement, each taking a given lot at the par price stated by the valuer, but if any overlapping occurs, and more than one purchaser desires one particular lot, the estate is then allotted by private competition amongst the intending purchasers. No purchaser is then at liberty to bid below par, each lot is knocked down to the highest bidder, and any premiums obtained are put into the common fund, and at the winding up of the estate, if any surplus remains it is returned as a bonus to the respective owners. If, on the other hand, there is anything short, a levy is made upon them on the same basis.

While the pioneers of the society were to a large extent horticulturists, amateur or professional, and their primitive idea was intensive culture, the society has since grown rapidly in numbers and broadened in character, so that while the gardener, or fruit and vegetable grower, is still as welcome as the flowers in spring, he finds himself associated with all ranks and conditions of men. Upon each estate a small colony is gradually rising up, houses are being built and occupied, and the farmer and country tradesman who looked at first with some suspicion upon their new neighbours, begin to realise that the enterprise means the expenditure of a large amount of capital, in some cases as far as £10,000 in two years, and that the locality cannot fail to be benefited by it. The members of this society are ever on the look out for land that can be occupied without sacrificing existing occupation. This enables them to purchase with confidence, and being assured that what capital and labour is spent on it is their own, it is safe. Single handed the members found themselves in difficulties to obtain land in small quantities, and in desirable places and conditions, so they have voluntarily combined to purchase and divide at cost price.

The Stocksfield estate comprises two hundred and six acres, and the number of purchasers is sixty-six; the areas bought being from one to twenty acres. In some cases no limit has been placed upon the value of the dwelling houses to be erected upon the estate, but plans are submitted to all the owners before erection, a plans committee being appointed to advise. The proprietors have thus guarded against the disfigurement of the estates. Undesirable industries have been debarred and public-houses have been placed amongst the forbidden, although not all the purchasers are abstainers. For purposes of allotment this estate was divided into one hundred and seventy-four parts in area from three-quarter to three and a half acres, and after an exciting competition, the whole were disposed of, and a total sum of over £1,200 realised in premiums. This amount goes to the general fund, for road making, draining, &c. On some of the estates large numbers of half-acre plots are sold, to suit members who desire them. The purchase and division of the estates during the last seven years has met a long-felt want, and the sound business manner in which the undertaking has been promoted has inspired confidence in the members, many of whom are inclined to procure a slice of land on which they may carry on their own industry.

Gardening in the lower parts of the Tyne Valley is conducted under many difficulties. There is a combination of injurious conditions—frosts; extraordinary wind from the west; smoke, with ash and soot wafted long distances; and, worst of all, deleterious gases. There are some districts where a gooseberry bush cannot be grown to be of any use. On the higher ground, however, the air is purer, and bush fruit and vegetables can be grown with success. Through the south and east side of the county there are large numbers of pitmen who have gardens, and many of them are expert in the cultivation of certain vegetables, notably the leek and onion, and some are enthusiasts in special flowers. The competition fostered by local horticultural societies has been useful in promoting the proper keeping of allotments, and will, no doubt, continue to extend its usefulness. One society for many years gave prizes for the best kept allotments, and a few of these have been under very high cultivation, and should have been object lessons in orderly arrangement and cleanliness. Such prizes are now withdrawn, as it was found only a small number entered for competition. Pitmen do not grow much fruit, as their vocation is very uncertain. The apple is very rarely planted in allotments in this county, as the gardens are too public, and fruit cannot be protected. In our district allotments have been freely granted during the last fifty years, and there are several fields divided into allotments, mostly one-tenth of an acre each. There are between four hundred and five hundred allotments in the vicinity of Alnwick, exclusive of the large number on the freemen's land on Alnwick Moor. These slices of land are much sought after by working men, both for pleasure and profit. Alnwick is a cold district, but the allottees who aim at high cultivation provide shelter. In some cases wood fences are raised on three sides, and berry bushes on the fourth; inside this shelter the higher art of allotment culture is performed. Some holders have a small greenhouse, and grow cucumbers and tomatos.

Celery, leeks, and onions receive special care and protection in the open, and the earliest celery has to be sown in the middle of February, and kept in a little heat to be suitable for planting in the open at the end of May. To avoid checks from drought, pipes are frequently placed at intervals in the trenches, the bottom end about the depth of the roots, and all liquids are poured down these pipes, care being taken that the soil does not become stagnant. Blanching is usually done with brown paper covered with soil. The leek is largely grown, as it is hardy, and a desirable vegetable, but it is not everyone who can grow first-rate samples. Here they are treated much the same as celery, some growers using wire netting round the plants, packing inside this with moss to blanch and shelter the leeks. If seed is sown in a frame or in a sheltered south aspect in February, good leeks can be grown in Northumberland. Of onions, the autumn-sown are managed best in this district, and from the 9th to the 12th of August is the best time to sow. With the exhibitors Cranston's Excelsior is the most highly esteemed variety, but it will not keep in the autumn. Sowing in the open commences any time after February 15, and as soon as the land is dry enough. The growers trench in part of the manure when the land is dug in December, then at sowing time they dig in good decayed manure near the surface. They believe that the onion is a gross feeding plant, and so sow the seed practically in the manure, and the previous manure being incorporated through the soil at good depth there is plenty to feed a good crop.

Potatos are the main crop in all allotments, and as the land is perpetually cropped with potatos it is advisable to apply lime at intervals of four or five years. There is great competition among allotment holders with potatos, and I have noticed through many years that a large number of the collections for competition at the Alnwick show have been large and coarse. The potato is for use at the table, and therefore very large tubers are out of place, and their quality is not so good as medium-sized tubers. This may be partly the fault of the judges giving prizes to large tubers. There is another word of criticism I would offer, and that is upon the state of the major part of allotments after the crops are taken away. The potato haulm is often left littered over the ground, with weeds and other refuse, all the winter. How much better it would be for the land, and one's character for neatness, if, when the crops were taken off, everything was cleared up and the land dug. It is always better trenched two spits deep where the land is deep enough, mixing in the manure. The manure is then being prepared for the food of plants by the time the crop is planted in the spring. Many protest against winter digging of heavy land, finding it better to dig in the spring.

There are some allottees who grow strawberries, and these form a valuable crop where grown well. When lecturing for the County Council five years since I stated that one hundred pounds sterling could be made out of a carefully cultivated acre of strawberries, and that amount had frequently been far exceeded. This was too much for some of the hearers, but among them was one anxious to improve his several acres of land. He invited me to see his holding, and I gave him all the information I could. Last autumn he called specially to see me, and stated that, having put my assertions to a severe test, he was thoroughly satisfied, because he had exceeded the result of £100 per acre. Yet he knew nothing about the cultivation of strawberries previously, and the circumstances were not so favourable as with very many, for he was situated five miles from a station and twenty miles from the principal market where the fruit was sold. I also pressed the holders to plant apples on the Paradise stock, and they have done so in the district and are satisfied. I gave them grafts of such free cropping apples as Lord Suffield, Stirling Castle, and Lane's Prince Albert, the latter perhaps the greatest general cropper we have, and my visitor declared that the grafted trees were then hanging with fruit, and the desire was for more apples.

Alnwick Castle Gardens. GEORGE HARRIS.

Echeveria farinosa.—Those who in their garden decoration still find pleasure in carpet or succulent bedding will find in this echeveria a charming plant for their purpose. It is not a coarse plant, indeed is dwarf habited. Its thick fleshy leaves are long and pointed, and give it very much the appearance of a thick white-leaved seedling carnation. The primrose character, however, is very marked. It propagates readily, and should be much more in favour than is the pretty white E. Peacocki, which is all the same so chary of increase. We saw this pleasing variety in quantity at Swanley recently, where it figures prominently in the remarkable collection of succulents which Messrs. Cannell and Sons have gathered together. It is interesting to learn that not only does the membership of the Cactus Society now reach one hundred and fifty, but also that a publication specially devoted to succulents and cacti is about to issue from the midlands. Probably the softer-leaved section, especially those dwarf and easily increased, which have been utilised for bedding purposes, are the most popular with gardeners generally.—A. D.

Carnation Yule Tide.—This promises to become, when better known, one of the most popular winter-flowering varieties that has been introduced for some years. The flowers are bright scarlet in colour, large, and of good form, and are produced upon stout footstalks, which are of sufficient length and strength to support them erect upon the plant, and to enable them to be effectively arranged when required to be used as cut flowers for vase decoration. A fine stand of blooms was staged at the Carlisle Chrysanthemum Exhibition in November last by the raiser, Mr. John Forbes, Hawick. These, it was stated, were cut from plants that had been flowering continuously for twelve months; this fully establishes its perpetual-flowering character, and although there are already some good scarlet varieties in this class, of which "Winter Cheer" is probably the best, yet, the free sturdy habit of Yule Tide should recommend it for cultivation and producing flowers in quantity during the dull winter months. The exhibit referred to was a centre of attraction to visitors to the exhibition, and was unanimously awarded a first-class certificate by the judges.—JAMES DAY, *Galloway House, N.B.*

WORK FOR THE WEEK.

COOL ORCHIDS.

WE have now entered the month of March, and, as the days are lengthening and the sunlight becoming stronger, ventilation must be allowed freely on all suitable occasions, both day and night; beware, however, of piercing east winds which are so prevalent during this month, and oftentimes accompanied by bright sunshine. At such times it is bad practice to give air simply to reduce the temperature, and to avoid this the roller blinds should be let down, the heat in the hot-water pipes reduced, and bottom ventilation given on the leeward side. Cool orchids may now be watered more freely without much fear of bad results following. Ada aurantiaca requires an abundant supply of water at this season, as it is rooting freely and will soon be showing its flower spikes. Cœlogyne (Pleione) lagenaria, C. Wallichiana, and C. Reichenbachiana are now growing freely. These plants are best grown on a shelf near the glass, at the warm end of the cool house, and should have all the light obtainable; water should be given without stint, and occasionally some weak liquid cow manure. In fine weather it will be beneficial to syringe these plants once or twice daily. C. humilis, and C. Hookeriana, having passed out of bloom, should be repotted at once, using a compost consisting of fibrous peat, loam, and chopped sphagnum in equal proportions, with a little coarse sand intermixed; water should be sparingly afforded until the plants have become well rooted. Disas are now growing freely, and should receive copious supplies of rainwater at the roots, frequently syringing them in order to keep red spider and thrips in check. The coolest end of the odontoglossum house will be found the most suitable place, as these plants delight in plenty of air and moisture. Bletia hyacinthina, B. h. albo-striata, are now showing signs of growth, and if repotting be necessary, should be at once attended to, using a compost of fibrous loam, finely chopped sphagnum, small crocks, charcoal, and clean coarse silver sand, the whole being well mixed together; place about two inches of drainage in the bottom of the pots, covering with a layer of rough peat or moss. A light position in the cool house is the best place for them, giving water freely until flowering is past, when it must be gradually withheld, and the plants stood in a sunny position to mature.

Oncidium ornithorhynchum is a free growing and floriferous species, producing branching spikes bearing a number of small sweet-scented flowers; these should now have fresh material afforded as the thread-like roots push out when the new growths are only a few inches high; the warm end of the cool house suits this orchid admirably. Oncidium leucochilum that has finished flowering should be kept dry until growth recommences, when it should be repotted. O. incurvum now making new growths should be potted if necessary, giving abundance of water during active growth, and reducing the supply when the bulbs are made up. Odontoglossum Rossi, O. Cervantesi, and O. Humeanum are three very pretty little orchids in flower at the present time, and care should be taken not to over-water the plants, always allowing the compost to become moderately dry before giving more water. O. Halli, O. maculatum, O. luteo-purpureum, O. triumphans, and O. gloriosum are also in flower. Some of the latter are very sweet-scented, while others have but very little fragrance; these all require the same treatment as O. crispum. Anguloa Clowesi, known as the Cradle Orchid, is very interesting the beautiful yellow cup-shaped flowers being highly perfumed. Any plants that require repotting should be attended to as soon as the flower spikes appear, for if left until they have passed out of flower the new roots will be too far advanced, and repotting be both difficult and dangerous; well drained pots should be used, and the compost should consist of two parts of fibrous peat and loam to one of sphagnum moss. These plants should occupy a position near the glass in the cool house; they require a good supply of water during growth, but very little during winter. After the new pseudo-bulbs have finished their growth a good period of rest is necessary. Vanda Kimballiana and V. Amesiana having now commenced to grow should be given more root space if necessary, using teakwood baskets, clean sphagnum, and a few pieces of charcoal, good drainage being, of course, essential. These species may be grown successfully at the warm end of the cool house, choosing a light airy position, and giving abundance of water during the growing season.—E. SHILL, *New Hall-Hey Gardens.*

KITCHEN GARDEN.

AS soon as the ground can be worked, it should be prepared to receive the onion seed. Some may say that this piece of advice is too late, as in warm districts the seed may already have been sown. Those, however, who dug the ground as previously advised after the crop of celery had been consumed, and allowed it to remain rough until the present time, will not be behind with the weight of their crop at the time of lifting. Choose a fine day, and sow the piece intended for onions with soot at the rate of one bushel to three perches of ground; this should then be forked in, reducing the soil to a fine powder in the operation. When sufficiently dry on the surface tread the whole plot firm, afterwards raking it smooth and level. There is no necessity for forming beds, as quite as good bulbs can be grown on the flat, and where the ground is light and dry this is far better, as the moisture is retained longer in the soil when not raised. Drills should be drawn about fifteen inches apart, and about half an inch deep. When the seed is covered deeper, there are usually too many thick-necked specimens. Sowing should be done carefully, for often far too much seed is used, and the plants crowd each other and become spindly. Covering should be done by raking the ground the same way as the drills are drawn, finishing off by trimming up the ends of the plot. A pinch of parsnip seed may also be put in now, but for a general crop sowing had better be deferred until the end of the month, particularly where the ground is rich, as the roots will be quite large enough by the autumn. Carrots, such as Model, Gem, and Early Horn, may also be sown in the open quarters where the soil is light and dry, but where heavy the sowings should for the present be confined to the warm borders. Peas sown in pots about the middle of January have, owing the mildness of the weather, made good progress, but it is scarcely safe to plant them out unless in warm, sheltered places where protection can be afforded. On warm borders, or at the foot of a south wall, they will not take any harm if planted now, but in cold localities it is well not to be in a hurry. When planting take out a trench across the plot or border rather deeper than the ball of earth in the pots, and, having turned the plants out, press the soil firmly round them. We usually treat about a thousand pots in this way, which give about seven hundred feet length of rows. The varieties to be turned out here are Gradus, Early Morn, Exonian, Early Marrow, Sutton's Seedling, Early Giant, Dwarf Defiance, Daisy, Excelsior, and Productive. A goodly number, no doubt, but then they do not all come into bearing at once. The dwarf early varieties sown in the open ground are all looking well, and these consist of Chelsea Gem, Sutton's Forcing, Carter's Forcing, and a few others. A sowing may now be made in the open quarters of such varieties as Telephone, Telegraph, Duke of Albany, Duke of York, The Don, or any of the above-named, whichever is considered best. Another sowing of broad beans may also be [illegible] choosing such varieties as Masterpiece, Green Giant, or Longpod.

Vegetables in pits or frames will now need more attention. Those that are forward should have all the air possible to strengthen their [illegible] and put colour into the foliage; those showing bloom must be [illegible] watched for mildew, and should on no account be allowed to [illegible] want of moisture at the roots. This is not one of the [illegible] to force, but this season has been an exceptional one, so that plants have [illegible] remarkably well. French beans will now make rapid progress, therefore sowings should be made at intervals to suit the requirements of the place. Continue to introduce seakale into a place where sweet crisp growth can be made. Here in the south that which was covered up on a north border will be ready for use in about a fortnight should the weather continue mild. Outside vegetables of all kinds are plentiful and good, therefore there has not been such a demand for forced ones as is sometimes the case. Turnips, carrots, radishes, lettuce, onions, and such things on hotbeds must be well supplied with air whenever the weather is favourable. In the southern districts it will not be necessary to lift any more asparagus roots for forcing as the growths will soon be showing themselves through the soil, and where glass lights have been placed over the beds the sun will have brought the plants forward. Those in frames that are becoming exhausted will be greatly benefited by having a dressing of fish guano to be washed in by warm water. Continue to make small sowings of mustard and cress, and keep up a supply of blanched salads by introducing more into the blanching place as the others become exhausted. A pinch of celery seed may be sown to give a supply of early plants. If placed in a brisk heat the seed will soon germinate. It is not advisable to sow too thickly as the plants soon become drawn and are of but little use afterwards.— H. C. PRINSEP, *Buxted Park Gardens.*

HARDY FRUITS.

WITH so mild a season, the trees on warm walls are much too forward for the time of year, consequently, protecting material must be held in readiness against severe weather. In previous notes I have advised covers which do not exclude air, and those which do not cause the trees to be darkened, as this weakens the bloom of apricots, &c., and causes it to drop; indeed, it would be best not to protect at all than to cover too much. Newly-planted fruit trees will now need attention. Leading shoots and others may now be shortened, but, as a rule, newly-planted trees are checked by their removal, and do not make much growth the first season, and even should any grow at all freely, one can easily cut back green shoots, or, what is better, pinch them back in a young state. There should be no delay in mulching newly-planted trees; indeed, in some soils, it may be necessary to give water, as, under walls with a projecting coping, I [illegible] found the soil very dry, and in our district the rainfall this winter has been [illegible] slight. When mulching, it is well to use manure in a strawy condition, as heavy manure keeps the roots cold, and rich food is not needed. The mulch is to conserve the moisture. In all cases should the mulch be given before the spring is far advanced, so as to prevent the bark shrivelling. Peach trees, nectarines also are more forward than I have seen them for years, and in these cases pruning and nailing cannot be longer delayed. I always un-nail all young wood early in November to harden it, and also retard the flowering as long as possible, but [illegible] cannot be kept from the wall after the flower buds are showing colour, and even then nailing needs to be done with care to prevent injury. Many growers who crop heavily do not give the trees any too much room, but crowded trees are the first to become infested with greenfly, and suffer from mildew. American varieties of peaches need rather more care in pruning than our own, and I find it advisable to leave more spray or light wood, and not to rely too much on [illegible] on the strong shoots, as, though the fruits set freely, they drop badly in [illegible] weather or the least check in the way of drought.

Now is a good time to give exhausted fruit borders assistance in the way of top dressings with fresh soil, to which has been added such aids as will encourage new surface roots. Many fruit trees would be more valuable if the surface roots were given greater assistance. In some cases they are left many years without attention, and in the end form strong roots down in the poor soil which is not conducive to fruit formation. Cherries delight in these annual dressings, and even when new soil cannot be given, bone-meal spread liberally on the surface and raked in will do much good. In heavy clay soils, I have found wood ashes with bone-meal a splendid fertiliser, and if other manures are given later on it is of course advantageous, but I place much importance upon food given now just before leaf growth is active. Apricots fail in many soils, and in such it is well to encourage surface roots; they often suffer from lack of lime, and I have succeeded after repeated failures by using old mortar rubble or chalk in the soil, and [illegible] muriate of potash occasionally during growth. These remarks only apply to [illegible] where the soil is exhausted; to give the food now will, with general [illegible] encourage new root growth. Fig trees on walls have not needed the heavy covering usually given them, and though full early to uncover entirely, it is not wise to coddle them, and there need be no fear of injury if the wood was kept well thinned and hardened. It may be well to cut out old bare wood not needed, if at all thick, but I am not in favour of much pruning at this time of year, as like peaches and nectarines, the fig bears on the wood made last season, and with due attention to stopping, thinning, and removal of old fruiting wood as soon as the crop is cleared, there needs little to do at this season. Any trees that fail to fruit freely, may with advantage be root-pruned just before the trees commence to grow.—G. WYTHES, *Syon Gardens.*

FRUITS UNDER GLASS.

THE banana is to a great extent a neglected fruit, though good home-[illegible] bunches provide a much-appreciated change in the dessert, and the plant is [illegible] easily cultivated, provided it can be given sufficient heat and light. One [illegible] to it is that there is no absolute certainty as to its providing fruit at a [illegible] unless room can be found to grow a number of plants, but when the dwarf [illegible] Cavendishi only is grown, it is possible to arrange that most of the plants [illegible] ripen fruit at a time when other fruits are scarce. This banana is the best [illegible] grow, as it fruits quicker and takes up less room than any of the others [illegible] details of culture are simple. Most fruiting plants will, by the time the [illegible] begin to change colour, have produced at least one strong sucker [illegible] unless an increase in stock is desired only one should be permitted to grow [illegible] so that all the energies of the old stool shall be devoted to the [illegible] this sucker, and to the perfecting of its fruit. Nothing is gained by letting the plant stand after ripening begins, as the individual fruits will ripen in [illegible] on the bunch when this has been cut and hung up in a warm, dry [illegible] the grower is then free to deal with the sucker which should be carefully [illegible] from the old plant, and either potted up or planted out at once in the [illegible] is to occupy. Most growers advise potting up, and giving the sucker two [illegible] shifts, but I have obtained at least equal results with less labour by planting [illegible] at once in a rough and ready way. The plants were grown in boxes [illegible] feet square, sunk into the central bed of a span-roofed hot-house, and directly the old plant was cleared out the soil was removed, fresh soil put in, and the sucker planted firmly. The soil used was lumpy fibrous loam, decayed horse droppings, and a sprinkling of half-inch bones. Treated in this way care was necessary not to over-water at the start, but the plants soon became established, after which water could be freely given, and there was no further check to growth; the bunches of fruit so grown were bigger than those produced by plants grown by the shifting-on system. In my case no bottom heat was given, the spaces round the boxes being filled up with blocks of granite, broken up as if for road making, and I think this avoidance of bottom heat helped to keep the plants dwarfer than they are usually seen. A temperature of 65 to 70 degrees as a minimum, with the usual rise from sun heat, suits the plants, and the house should be frequently damped down, as a moist atmosphere is conducive to quick and healthy growth.

Early figs will be swelling fast, and where the crop is a heavy one, copious supplies of water will be necessary, liquid manure being given freely, but not too strong; this is a necessary caution when stable drainings form the supply, for this is highly charged with ammonia, the fumes of which are dangerous to the tender leafage. Trees planted out and grown on the extension system will require no stopping, except of such shoots as are over-grown, but may be disbudded freely, doing the work by degrees until only sufficient shoots are left to furnish the trees with bearing wood for next year. Pot trees require different management, as it is not possible to grow these on extension lines, therefore the young growths should be stopped when about eight or nine inches long. Such trees should be highly fed almost throughout their growth, but I like to reduce the supply of liquid manure to the roots during the period when flowering takes place, and the fruits are at a standstill as regards swelling. On the same principle I reduce at the same period the heavy drenchings given to planted-out trees, and content myself with keeping the borders just sufficiently moist, as experience has taught me that very heavy waterings at this period will cause a portion of the fruit to turn yellow and drop. Syringe the trees freely on all favourable occasions, choosing the mornings of days that promise to be bright, so that the leaves and fruit will become dry before night. Syringing is a very necessary attention to keep down red spider.

Strawberries, having set their fruits, should be thinned as soon as it can be seen not only which are the best-placed fruits, but also whether these are well set and likely to be shapely; it is better to retain small fruits than deformed ones. I do not advocate very severe thinning of such sorts as Vicomtesse Hericart de Thury and Keen's Seedling, but each grower must be guided by his requirements as to the number left on the plants. Those mentioned will easily carry ten to twelve fruits in a six inch pot, but if large fruits are necessary, and room plentiful enough to admit of big patches being forced, a less number must be left. When the fruits commence to swell liquid manure should be given frequently, and I find that it is best to vary the manure, giving alternate waterings of liquid sheep manure and guano, the latter in a weak and clear state. Fresh batches should be introduced to the forcing house as frequently as room can be found for them, so that there shall be no break in the supply. Each batch should be cleaned by dipping in some insecticide before being placed in the house.—J. C. TALLACK, *Livermere Park Gardens.*

THE ACCOUNTS OF THE NATIONAL CHRYSANTHEMUM SOCIETY.

To the Editor of the GARDENERS' MAGAZINE.

MR. GEORGE GORDON when criticising some of the items of expenditure in the financial statement placed before the annual general meeting on Monday, drew a contrast between the amount of show expenses charged in the financial statement for 1891, namely £12 16s. 3d., as against that of £32 7s. 5d. in last year's statement. I think Mr. Gordon was a little wanting in consideration for the secretary in not giving him notice that it was his intention to call attention to this item, for though it was not necessary he should do so, common courtesy suggests this would have been the proper course. In 1891 three exhibitions were held at the Royal Aquarium. In the financial statement for 1891, three items comprised the show expenses, viz., hire of plants, £18 15s. 9d.; cartage, £11 0s. 6d.; show expenses, £12 16s. 3d.; total, £42 12s. 6d. I now take the three same items for 1897, when four shows were held, all of considerable dimensions, the November one especially: Hire of plants, £6 15s.; cartage, £4; show expenses, £32 7s. 5d.; total, £43 2s. 5d.; only 9s. 11d. more than in 1891, with all the difference in the number and size of the shows. The fact is that when I took office at the end of 1890, I found myself the inheritor of a system which went to reduce the show expenses proper by taking from that amount, in order to make it appear small, and heaping it on to cartage and hire of plants. In 1892 I again followed the lead of my predecessors when making out the statement, and then the account appears: Hire of plants, £19 7s. 6d.; cartage, £14 1s.; show expenses, £16s. 13s. 4d.; total, £50 1s. 10d.; that year an October show, and a much more extensive one, was substituted for the December one. In the statement for 1894 (four shows being held that year) I determined to put the show expenses in their actual proportions, and they read: Cartage, £6 19s. 10d.; hire of plants, £4; show expenses, £36 13s. 10d.; total, £47 3s. 8d. One more contrasting year, that of 1889, before I became the secretary. Three shows were held this year, viz., September, November, and a small mid-winter exhibition in January. The self-same figures appear thus: Hire of plants, £17 6s.; cartage and labour, £17 10s. 2d.; show expenses, £18 5s. 8d.; total, £55 1s. 10d. In 1895 these three items came to £52 18s. 3d. In 1897, notwithstanding the expansion of the shows, the same items amount only to £43 2s. 5d. I have honestly endeavoured in the face of mounting up of the value in the schedules of prizes to keep these expenses as low as possible; and as a substantial proof of this, I simply ask for a comparison of the figures 1895 with 1897. In conclusion, allow me to remark that a great deal has been heard of late about the Edinburgh show, which is held up as a model for London to shape a show by. I have the expenditure of this show before me, and it is a revelation. In addition to music, rent, printing, and advertising—these four items amounting to £426 9s. 9d. for one show—there is in addition fitting up markets, £103 18s. 4d.: general show expenses, £120 12s.; secretary's expenses, £17 12s. 3d.; treasurer's expenses, £11 2s. 8d. Contrast these three items of show expenses for *one* exhibition with the very moderate sum of £43 2s. 5d charged for *four* exhibitions to the National Chrysanthemum Society.

RICHARD DEAN, Secretary.

MR. GEORGE PAUL, head of the firm of Messrs. Paul and Son, rose growers and nurserymen, Cheshunt, has been made a justice of the peace for the county of Hertford.

EXHIBITIONS AND MEETINGS.

READING GARDENERS' ASSOCIATION.

THE fortnightly meeting of the above association was held in the Club Room, British Workman, on Monday last, the president, Mr. C. B. Stevens, presiding over a good attendance of members. The subject for the evening was "A Chat about Melons," introduced by Mr. B. Dockerill, The Gardens, Elmhurst, Reading, a well-known grower and successful exhibitor of this fruit. The paper was of the most practical nature, and dealt with the cultivation of the melon in all its branches. Mr. Dockerill said he was obliged to condense a large subject into a small paper, but trusted that it would be sufficient to open up a good discussion on the principal points worth considering, for the melon was a fruit so widely known that it was reasonable to assume that there was hardly a gardener who had not made its acquaintance in one way or another, and it would be difficult to find a garden of any dimensions where these excellent fruits were not grown. The requirements for their successful cultivation were not large, for they may be summed up in the following words: Heat, moisture, fresh air, sunshine, and good soil. Span-roof houses were preferred, standing in an open situation running from north to south, and frames made on the same principle were certainly preferable to the lean-to. After dealing with the inside arrangements of the house, particulars were given as to the making of the borders, the best soil to be used, raising of the seed, the system of planting, stopping, topdressing, temperature, ventilation, watering, &c. As to the varieties, after briefly referring to the sorts of bygone days, such as William Tillery, Reid's Scarlet Flesh, Victory of Bath, &c., the qualities of many of those grown at the present time were touched upon, the foremost position as the best for all purposes, whether for growing in houses, frames, for exhibition, or for flavour, was given to that grand variety, Hero of Lockinge. In conclusion, the diseases to which the plants were subject were referred to, and also the growing of melons for exhibition, a practice in which the speaker had been exceedingly successful for at the Reading Horticultural Show, in 1892, in a competition for a brace of melons (fourteen entries), and for a single specimen (twelve entries), Mr. Dockerill was awarded the highest honours in both classes, and as late as 1896 he again took first prizes in both classes, the fruit in each case being grown in frames.

An interesting and profitable discussion ensued, in which Messrs. M. H. F. Sutton, Turton, Martin, Woolford, Bound, Hobbs, Neve, and the President took part. A hearty vote of thanks was given to the lecturer for his very practical paper. Exhibits were small in number, but interesting. Mr. Thompson, gardener to F. Wheeler, Esq., Tylehurst, exhibited a two-spathed arum; and Mr. Dockerill some excellent blooms, equal in quality to those seen in November, of Mrs. E. W. Clarke and J. H. Taylor chrysanthemums.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE annual meeting of this society was convened for Thursday, February 28, at Anderton's Hotel, Fleet Street, at seven o'clock. There was one of the largest gatherings we have seen on such an occasion, and the proceedings were of a more animated character than usual. The chair was taken by Mr. T. W. Sanders. The usual formalities, such as the reading of notices, minutes, &c., were soon transacted, and then the chairman called upon the secretary, Mr. R. Dean, to read the report and financial statement of the committee for the past year.

REPORT OF THE COMMITTEE, 1897.

At the termination of another year's operations, your committee can congratulate the members upon the steady and satisfactory progress still being made by the society; its work during the past twelve months was carried on with energy and success; its resources are as great as ever; its supporters more numerous; it is financially sound; and its prestige knows no diminution. During the year four exhibitions were held. and, as is usual, they were of a high order of merit. The meetings of the Floral Committee maintain their interest and usefulness, and the societies in affiliation show a substantial increase. In common with some kindred societies, your committee took steps to commemorate the Diamond Jubilee of her Majesty the Queen, by instituting some special classes, which were competed for at the November show, and proved interesting features. A Commemoration Fund was opened, and a fair proportion of the amount offered as special prizes obtained.

The Jubilee edition of the catalogue, 1896, is still in constant demand; it has been found most useful by affiliated societies, and it will be gratifying to the compilers to know how greatly it is appreciated. Inquiries are being made as to the probable issue of a supplement; a desire is also occasionally expressed that the publication of a year book be continued if possible. The Classification Committee have held a sitting, and dealt with certain varieties of incurved flowers, defining their proper pssition. This committee has sought and obtained from the General Committee larger powers, which will enable them to make from time to time such recommendations affecting the exhibition of plants and blooms which it may appear desirable to adopt in practice. A sub-committee has been entrusted with the revision of the rules, and after full and patient consideration have recommended material alterations, which they believe will, if adopted, improve the procedure of the society in several particulars, and bring the rules generally into closer agreement with its practice.

During the year ending December 31st, thirteen Fellows and one hundred and fourteen ordinary members have been elected to the society, and the number of societies in affiliation have increased by eleven. An agreement has been entered into by your committee with the Royal Aquarium Society to hold four exhibitions in the present year, viz.: in September, October, November, and December; and the directors commemorate the fact that the National Chrysanthemum Society has held their exhibitions at the Aquariam for the past twenty-one years by offering special commemorative prizes at the November exhibition. The schedule of prizes for the four exhibitions have undergone revision, and a substantial increase in money value has been made in several leading classes. A special class for twelve vases of specimen blooms of Japanese chrysanthemums has been introduced at the November show; the president, Sir Edwin Saunders, generously giving the first prize of £20.

Your committee most heartily thank the President, as well as all donors of special prizes at the various exhibitions, as they are frequently the means of bringing out some novel features, adding to the attractiveness of the various shows: and highly appreciate the warm interest Sir Edwin Saunders takes in the work and success of the society. Your treasurer, Mr. J. R. Starling, who has been connected with the society by membership since 1878, who was appointed treasurer in 1879, and has held that office ever since, is compelled by ill-health to insist upon the resignation of that office, he, for the same reason, placed in the hands of the members a year ago. Your committee also regret the death of Lord De L'Isle and Dudley, one of the patrons of the society.

FINANCIAL STATEMENT.

Expenditure.	£	s.	d.
Prizes at four shows, including medals	532	16	0
Prizes outstanding	1	0	0
Affiliated societies, &c.	90	19	0
Cartage	4	0	0
Judges' fees	18	18	0
Judges, floral, and staff luncheons	24	2	6
Bill-posting	12	9	8
Advertisements in horticultural press	13	2	0
Hire of bottles	2	1	2
Hire of plants	6	15	0
Hire of rooms	8	18	0
Expenses of annual dinner	18	5	3
Printing	64	18	9
Printing Jubilee catalogue	60	3	6
Stationery	19	10	1
Petty cash, stamps, telegrams, &c.	50	15	10
Royal Aquarium Company, tickets	17	10	0
Clerical assistance	77	2	0
Show expenses	37	2	5
Commission on advertisements in Schedule	2	17	0
Foreign Corresponding Secretary's account	1	17	0
Floral Committee expenses	3	18	9
Insurance premium	0	7	6
Donations to Royal Aquarium Company	2	2	0
Testimonial to J. W. Wilkinson	5	5	0
Illuminated addresses to secretaries	6	18	0
Sundry expenses	4	7	0
Paid to reserve fund	0	12	4
Bank charges	0	14	11
Balance in hand	38	16	2
Total	£1,123	9	10

Receipts.	£	s.	d.

Members' annual subscriptions	298	11	0
Foreign members' subscriptions	6	2	0
Donations and special prizes	73	7	6
Royal Aquarium Company, for three shows	300	0	0
Bill-posting, as per contra	12	9	8
Entry fees and rent of space	115	14	0
Affiliation fees	75	1	0
Medals and certificates, from affiliated societies	121	4	6
Sale of catalogues	9	12	8
Sale of tickets	19	2	6
Advertisements in schedule	36	2	0
Advertisements in catalogue	45	0	0
Reserve Fund	0	12	4
Total	£1,123	9	10

A further statement was then read by the Secretary, showing the society's outstanding liabilities, chiefly printing and medal accounts, to amount to just over £85. The assets, including a valuation of trophies, cups, tickets, stationery, catalogues, arrears of subscriptions, and the balance shown by the financial statement, amounted to over £124, leaving a balance in favour of the society of £38 12s. 6d.

The Chairman then rose to move the adoption of the report, which he did formally, remarking that in his position as chairman of the committee he thought it advisable neither to find favour or fault with the report or accounts. The motion was seconded by Mr. H. J. Jones.

The Treasurer (Mr. Starling) observed that he had now occupied the post of treasurer to the society for the past twenty years, and during that period he had seen the once small body increase and assume gigantic proportions. He felt that the duties were now more than his failing health and spare time allowed him to perform to his own satisfaction, and consequently he was resigning his office. In doing so he did not fully agree with the accounts as set forth, because, though a balance to the good was shown, it still remained a fact that they were nearly £100 in debt, and they had not the money to meet the outstanding liabilities unless the reserve fund was sacrificed. He suggested that paid auditors should be obtained—he placed no imputation upon those who had in the past fulfilled such duties, but thought independent men should do duty. With reference to the reserve fund, Mr. Starling showed that at the end of 1896 it consisted really of £45 for the addition of £55, making up the present £100, was made from a balance in hand shown on the accounts, but which was not really a balance in hand, as all the debts of that year had not been paid.

Mr. Dean replied that it was difficult to bring up all the accounts to date, as some of the expenses were incurred at a late period. There were some arrears to come in, and this, with the cash in hand, should meet most of the liabilities; then there was the reserve fund to fall back on. He felt justified in endorsing the committee's statement that the society was financially sound, and added that never before had it been so sound as at present,

Mr. G. Gordon, the next speaker, stated that Mr. Starling had cleared the way for what he wished to say with regard to the financial condition of the society. By carefully considering and comparing items in recent balance-sheets he had found that certain expenses had increased in a measure that did not seem to be justified; there were the show expenses, luncheons, and the expenses of the annual dinner: and with reference to the latter he considered it the duty of those who attended to pay a sufficient sum above the cost of the food to clear off some other expenses, such as music, hire of plants, &c., and not throw them upon the members who had not participated. The speaker showed that the balance in hand shown in the 1896 accounts was not the profit upon the year's working, because outstanding liabilities had not been met; but in view of such a balance medals and illuminated addresses had been given to the society's leading officers, when, in fact, they could not pay their way. This laid the society open to censure from outsiders at a time when they should gather their clothes about them rather than spread coat tails for others to tread upon. Notwithstanding all this and the present unsatisfactory position of the finances, Mr. Gordon stated that the committee had suggested a large addition of prizes and classes to the schedule for the current year; in fact they intended offering only £124 less in prizes than the amount offered at the Jubilee exhibition, when there was a special list of donations ([illegible]) to meet the accounts. The committee proposed giving in money and medals the sum of £580, exclusive of special prizes at the four forthcoming shows, and while he hoped the income from membership would increase, he failed to see where the money was forthcoming to pay the prizes and the necessary expenses of conducting the society's business. Now that the reserve fund would be practically wiped out in putting matters straight he could see nothing but disaster at the end of 1898 if the estimates were allowed. In view of such an end, and with the hope of checking such an increased expenditure, Mr. Gordon moved as an amendment that the report and financial statement be referred back to the General Committee, with instructions to prepare a more detailed account showing liabilities and assets, to prepare an estimate of the income and expenditure for the current year, and to consider the reduction of the number of shows, or the expenses connected therewith, in the present year.

Mr. J. W. Moorman seconded the amendment. He stated that the society owed £85 11s. 6d., and had only £38 16s. 2d. to meet the debt unless the reserve fund was sacrificed. Even this, he thought necessary, for the proposed treasurer had rightly made it a condition of his acceptance of the post, that all liabilities must be fully met. The speaker considered it absurd to value the envelopes, trophies, &c., and place them as assets, as had been done, for their market value was very small. He also referred to the recent smoking concert held on behalf of the funds of the society, instituted by its officers, and yet never brought before the General Committee to sanction or otherwise. He trusted the meeting would refer the accounts and report back to the committee in accordance with the terms of Mr. Gordon's amendment. Mr. Bevan supported the amendment, stating that Mr. Starling had again and again made similar observations to those made that evening, and it was now quite time they were heeded, for the proposed treasurer would not accept office until all liabilities were cleared off. Mr. Newell also supported the amendment, observing that he hoped the item for dinner to the Floral Committee would never again appear in the balance-sheet. He objected to much of the expenditure for luncheons and dinners, and thought that the annual dinner should be no expense to the society. Mr. Cholmondeley suggested that it would be but business-like to print and circulate the report and balance-sheet among the members previous to the annual meeting, so as to enable them to duly consider facts and figures. He regretted that at the meeting itself no such printed slips were in the hands of the members.

The Secretary explained that the increased expenditure proposed was due to the action of the Schedule Sub-Committee in increasing classes and prizes, an action he had objected to, because he foresaw that the society could not remain solvent if such expense was incurred. Mr. Willis asked for the auditors' certificate, which the Secretary read, remarking that there had not been sufficient time to print and hand round the financial statement since it was audited. The auditors commenced at half-past two, and finished at eight o'clock, after examining every voucher. These remarks brought Mr. Lees to his feet, and he briefly stated that, while a good deal of the blame had been placed upon the Schedule Sub-Committee, yet Mr. Dean had himself suggested the addition of several classes, and that he should have known and informed that committee of the present and probable future condition of affairs. Mr. Waterer also supported the amendment, remarking that the society did not participate in the profits its efforts realised to the extent it should. In reply to Mr. Moorman, the Secretary stated that the audit was held at the Aquarium Tavern instead of at Anderton's owing to an oversight with regard to the engagement of a room. A slight alteration having been made in the original amendment, it was now put by the Chairman as follows: It has been proposed by Mr. Gordon, and seconded by Mr. Moorman, "That the report and financial statement be referred back to the General Committee with instructions to prepare a proper balance-sheet, to prepare an estimate of the income and expenditure for 1898, and to report on the advisability of a reduction in the number of the exhibitions, or the prize money, during the current year, and to submit the same to an adjourned annual meeting." Messrs. Addison and Harman Payne having been appointed tellers, it was found that eighty-three voted for and six against it. The amendment then became the substantive motion, and was put and carried unanimously.

Mr. Cholmondeley, having formulated a proposition in accordance with his previous suggestion, moved that the accounts and report be printed and circulated among the members seven days before the annual meeting, so that they might come prepared to discuss matters. He did not think the society exactly on the eve of bankruptcy, but he felt there was a strong need of a detailed account of receipts, expenditure, and liabilities, and that this should be in the members' hands before the annual meeting, so that no one would be committed to what he had almost no opportunity of objecting to. This motion was seconded by Mr. Wooderson, and carried. Mr. W. Wells proposed that members be allowed to vote at the annual meetings by proxy, but he was ruled out of order, the chairman drawing attention to the rule demanding due notice of alteration of rules.

Mr. Spicer then moved that the meeting be adjourned for a month. Mr. [illegible] seconded the motion. Mr. Starling and Mr. Cholmondeley supported it, and Mr. Waterer suggested that the adjourned meeting be commenced at six p.m. instead of seven. The Chairman suggested that the adjournment be for three weeks, as a fortnight was not time enough, and a month would be putting it off rather long. The meeting finally decided to adjourn the annual general meeting until March 21 at six o'clock. It having been ascertained that the dining hall at Anderton's Hotel was available for that date, the proceedings closed with a vote of thanks to the chairman.

CARDIFF AND COUNTY HORTICULTURAL SOCIETY.

THE annual meeting for the appointment of officers, &c., was held on Monday, when a good number of members attended. A strong executive committee was formed, with Mr. A. E. Dixon as chairman, and Mr. A. W. P. Pike as vice-chairman. Mr. H. Gillett was re-elected secretary. The committee, after due consideration, decided to hold the annual show on July 20 and 21, which is [illegible] three weeks earlier than usual.

Classifying Onions for Exhibitions.—I am often asked how onions for shows raised from seed sown under glass in the winter are to be classified. The common classes are for autumn sown, and spring sown, these being the ordinary designations for onion classes prior to the introduction of the winter sowing practice. My suggestion is that, not to sit upon a practice which, if moderately productive of such good results, show committees should now include three classes as thus: "Outdoor autumn-sown," "Outdoor spring sown," and "Winter sown under glass." Thus those so raised, as it were artificially, would not compete on the show table with the bulbs produced under ordinary culture. As to the autumn-sown onions I should like to see them raise fewer of the worthless [illegible] Tripolis, and more of the brown or Spanish type so raised, as these will keep and be long useful.—A. D.

BULBS & SEEDS

BANKERS:
London and Midland Bank,
Ltd., Birmingham.

FOR SPRING PLANTING.

VERY SPECIAL AND IMPORTANT OFFER

OF ONE OF

The Largest Stocks held by any dealer in the United Kingdom, and at Prices which have no parallel.

NOTE.—All Bulbs offered are in splendid form, and good results are assured, for better quality cannot be had. Compare my prices, and note the immense advantages I give, which always secure a constant and increasing demand for my Goods from most of the extensive buyers throughout the country. So much is this so, that I, unlike the majority of dealers engaged in this business, have no necessity to advertise; and it is a solid fact, which speaks volumes as proof of the genuineness of this statement, that since early in October last until the end of February not a single announcement of mine has appeared in any Gardening Journal, during which time business has been carried on at full pressure in the most extensive Bulb and Seed warehouses in Birmingham or its neighbourhood, where a blank day is absolutely unknown. The principle at which I aim is—"Once a customer, always a customer;" and that I attain this desirable consummation is amply demonstrated by the fact that my patrons in 1885 are mine in 1898, and so long as they are buyers they will doubtless so remain, for I have never yet lost the patronage of an important buyer; but, on the contrary, I have now upwards of 10,000 customers, secured entirely through the kind recommendations of patrons who have proved my goods to be in every way as represented.

60,000 JAPANESE AND OTHER LILIES,

Every Bulb guaranteed perfectly sound, in fine form, and certain to flower.

AURATUM—Good Bulbs, varying in size, from 7 inches to 9 inches in circumference	4/- *per Case of* 30 *Bulbs*

AURATUM—Magnificent ditto, 10 inches to 12 inches ditto	12/6 *per Case of* 25 *Bulbs*
KRÆTZERI—Splendid Japanese Bulbs, averaging 10 inches in circumference	7/6 *per Case of* 20 *Bulbs*
MACRANTHUM—Good Bulbs, varying in size from 7 inches to 9 inches in circumference	10/- *per Case of* 20 *Bulbs*
MACRANTHUM—Splendid Bulbs; ditto, 8 inches to 10 inches ditto	14/- *per Case of* 20 *Bulbs*
MACRANTHUM—Magnificent Bulbs; ditto, 9 inches to 11 inches ditto...	20/- *per Case of* 20 *Bulbs*
MELPOMENE—Splendid Japanese Bulbs, averaging 10 inches in circumference	10/- *per Case of* 20 *Bulbs*
RUBRUM—Splendid Japanese Bulbs; ditto, 10 inches ditto. These Bulbs are far superior to the Dutch variety, producing flowers in greater abundance and of far larger size	5/- *per Case of* 20 *Bulbs*
ROSEUM—Good certain flowering Dutch-grown Bulbs, which cannot fail to give satisfaction. Observe this price	4/- *per Case of* 30 *Bulbs*
RUBRUM—Ditto ditto ditto	4/- *per Case of* 30 *Bulbs*
BELLADONNA (Amaryllis Belladonna)—Splendid Italian grown Bulbs	5/- *per Lot of* 30 *Bulbs*
VALLOTA PURPUREA (Scarborough Lily)—Very fine South African Bulbs	5/- *per Lot of* 20 *Bulbs*

AURATUM—Enormous Bulbs, guaranteed in no instance less than 12 inches in circumference. 6 Bulbs for 7/-; 12 for 12/-; or 17/6 per Case of 20 Bulbs.

MACRANTHUM—Enormous Bulbs, guaranteed in no instance less than 12 inches in circumference. 3 Bulbs for 7/-; 6 for 12/-; 12 for 21/-; or 30/- per Case of 20 Bulbs.

RUBRO-VITTATUM—Good certain flowering Bulbs. Observe these prices: 3 for 4/-; 6 for 7/-; or 12/- per dozen.

BROWNII—Good Bulbs of the true Japanese variety; guaranteed. 6 for 5/-; or 8/- per dozen Bulbs.

SPECIAL COLLECTION OF LILIES—All named.

COLLECTION No. 1 Comprises 3 Bulbs each of Rubro-Vittatum, Macranthum (12 inches), Auratum (12 inches), Melpomene (11 inches), Krætzeri (11 inches), Brownii, and Batemanniæ. Here is a splendid parcel indeed, cheap at £2, but my price is:—
20/- per Collection of 21 Bulbs, and all named.

COLLECTION No. 2 Comprises 3 Bulbs each, Macranthum (10 inches), Auratum (11 inches), Melpomene (10 inches), Rubrum (10 inches), Krætzeri (10 inches, Belladonna, extra large, and Brownii. This is another undoubtedly cheap parcel, my price being:—
10/- per Collection of 21 Bulbs, and all named.

Note.—*Buyers are requested to note that in no single instance can I divide the various lots specified above, and that when two or more Cases are ordered I reserve the right to pack the contents into one or more larger boxes. In every instance the goods will be most carefully packed and labelled, and therefore it is impossible that they can either get mixed or damaged in transit.*

All prices quoted throughout this announcement are "SPECIAL." They are in every instance strictly net for prompt cash with order for not less than the quantities specified. They do not include carriage, but no charge whatever is made for packing, cases, &c.

For Begonias, Gloxinias, Cannas, Dahlias, Gladioli, Hyacinthus candicans, Herbaceous Irises, Pæonies, Montbretias, Ranunculus, Spiræas, &c., see Special List,

FREE ON APPLICATION.

VEGETABLE AND FLOWER SEEDS.

Every season the demand for my Seeds increases, and rightly so, for no seedsman gives better value, nor is it possible to offer finer or purer strains than mine; space, however, will not admit of my giving here detailed descriptions of my stocks in this department of my business; therefore, it must suffice when I state that full particulars are given in my SPRING CATALOGUE for 1898, copies of which will be sent gratis and post free to all applicants. Early application is, however, necessary, the surplus now being very limited.

Cross all remittances "LONDON AND MIDLAND BANK, BIRMINGHAM," *and address all communications to*

J. G. CLARKE, Wholesale Bulb and Seed Importer, **57, 59, and 61, PERSHORE ST., BIRMINGHAM.**

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates.

Employment at Chiswick.—A. B. C., Batheaston: You had better apply to Mr. S. T. Wright, superintendent of the R.H.S. Gardens, Chiswick, Middlesex, who will give you full information. At Richmond, not far from Chiswick, science and art classes are held, while you could reach town for Birkbeck or Polytechnic classes easily, and by two different railway routes.

Chrysanthemum Madame Carnot.—C., Herts: In order to obtain first-class blooms of Madame Carnot, writes Mr. Lees, the plants must be grown well from the early stages onwards, and treated liberally with manures after the large pots are filled with roots. The plants should also be housed not later than September 20, and given a good light position, with the buds near the roof glass; this is to ensure perfect ripening of the growth, without which condition good blooms cannot be obtained. The bud must be taken about August 20, and is what is known as the second crown. It will be best for you to pinch a few plants on April 20, and allow others to make a natural break, which will take place about the end of April. The resulting second buds will present themselves about the desired time in ordinary seasons. It is important to bear in mind that early crown buds are useless, while very late buds give small blossoms, wanting in depth.

Clivea or Imantophyllum.—H. H., Richmond: The best time to divide and repot clivias is in the spring before growth commences. As your specimen is now flowering you must wait until the blooms have faded or have been cut. The plants make very strong roots and thus need a stiff compost; well drain new pots and use a sound substantial loam mixed with a little sand. Pot firmly and place in an intermediate temperature; little water will be needed at first but as the roots increase and growth becomes vigorous more will be needed. As soon as it is seen that no more leaves are forthcoming it will be time to afford more air and less water until a position in a cool pit or greenhouse will suffice during the winter. When well rooted clivias are easily forced, but it is a mistake to force them hard. Keep the foliage clean by frequent spongings, and use a soft brush to remove any insects that may lurk at the overlapping bases of the leaves. A piece of soft dry sponge is best for cleaning the foliage, provided the latter has not become too filthy to be thus dealt with

Highest Price of an Orchid.—A. H. L., Newport: Some of the highest prices recorded as being paid for orchids include Aerides Lawrenciæ, £246 15s.; Cœlogyne cristata hololeuca, £200; Cymbidium Parishi, £105; Renanthera Lowi, £105; Phalænopsis intermedia Portei, £100; Cypripedium Beeckmani, £160; Cypripedium Stonei platytænium, £147. We believe Odontoglossum crispum augustum sold for £300.

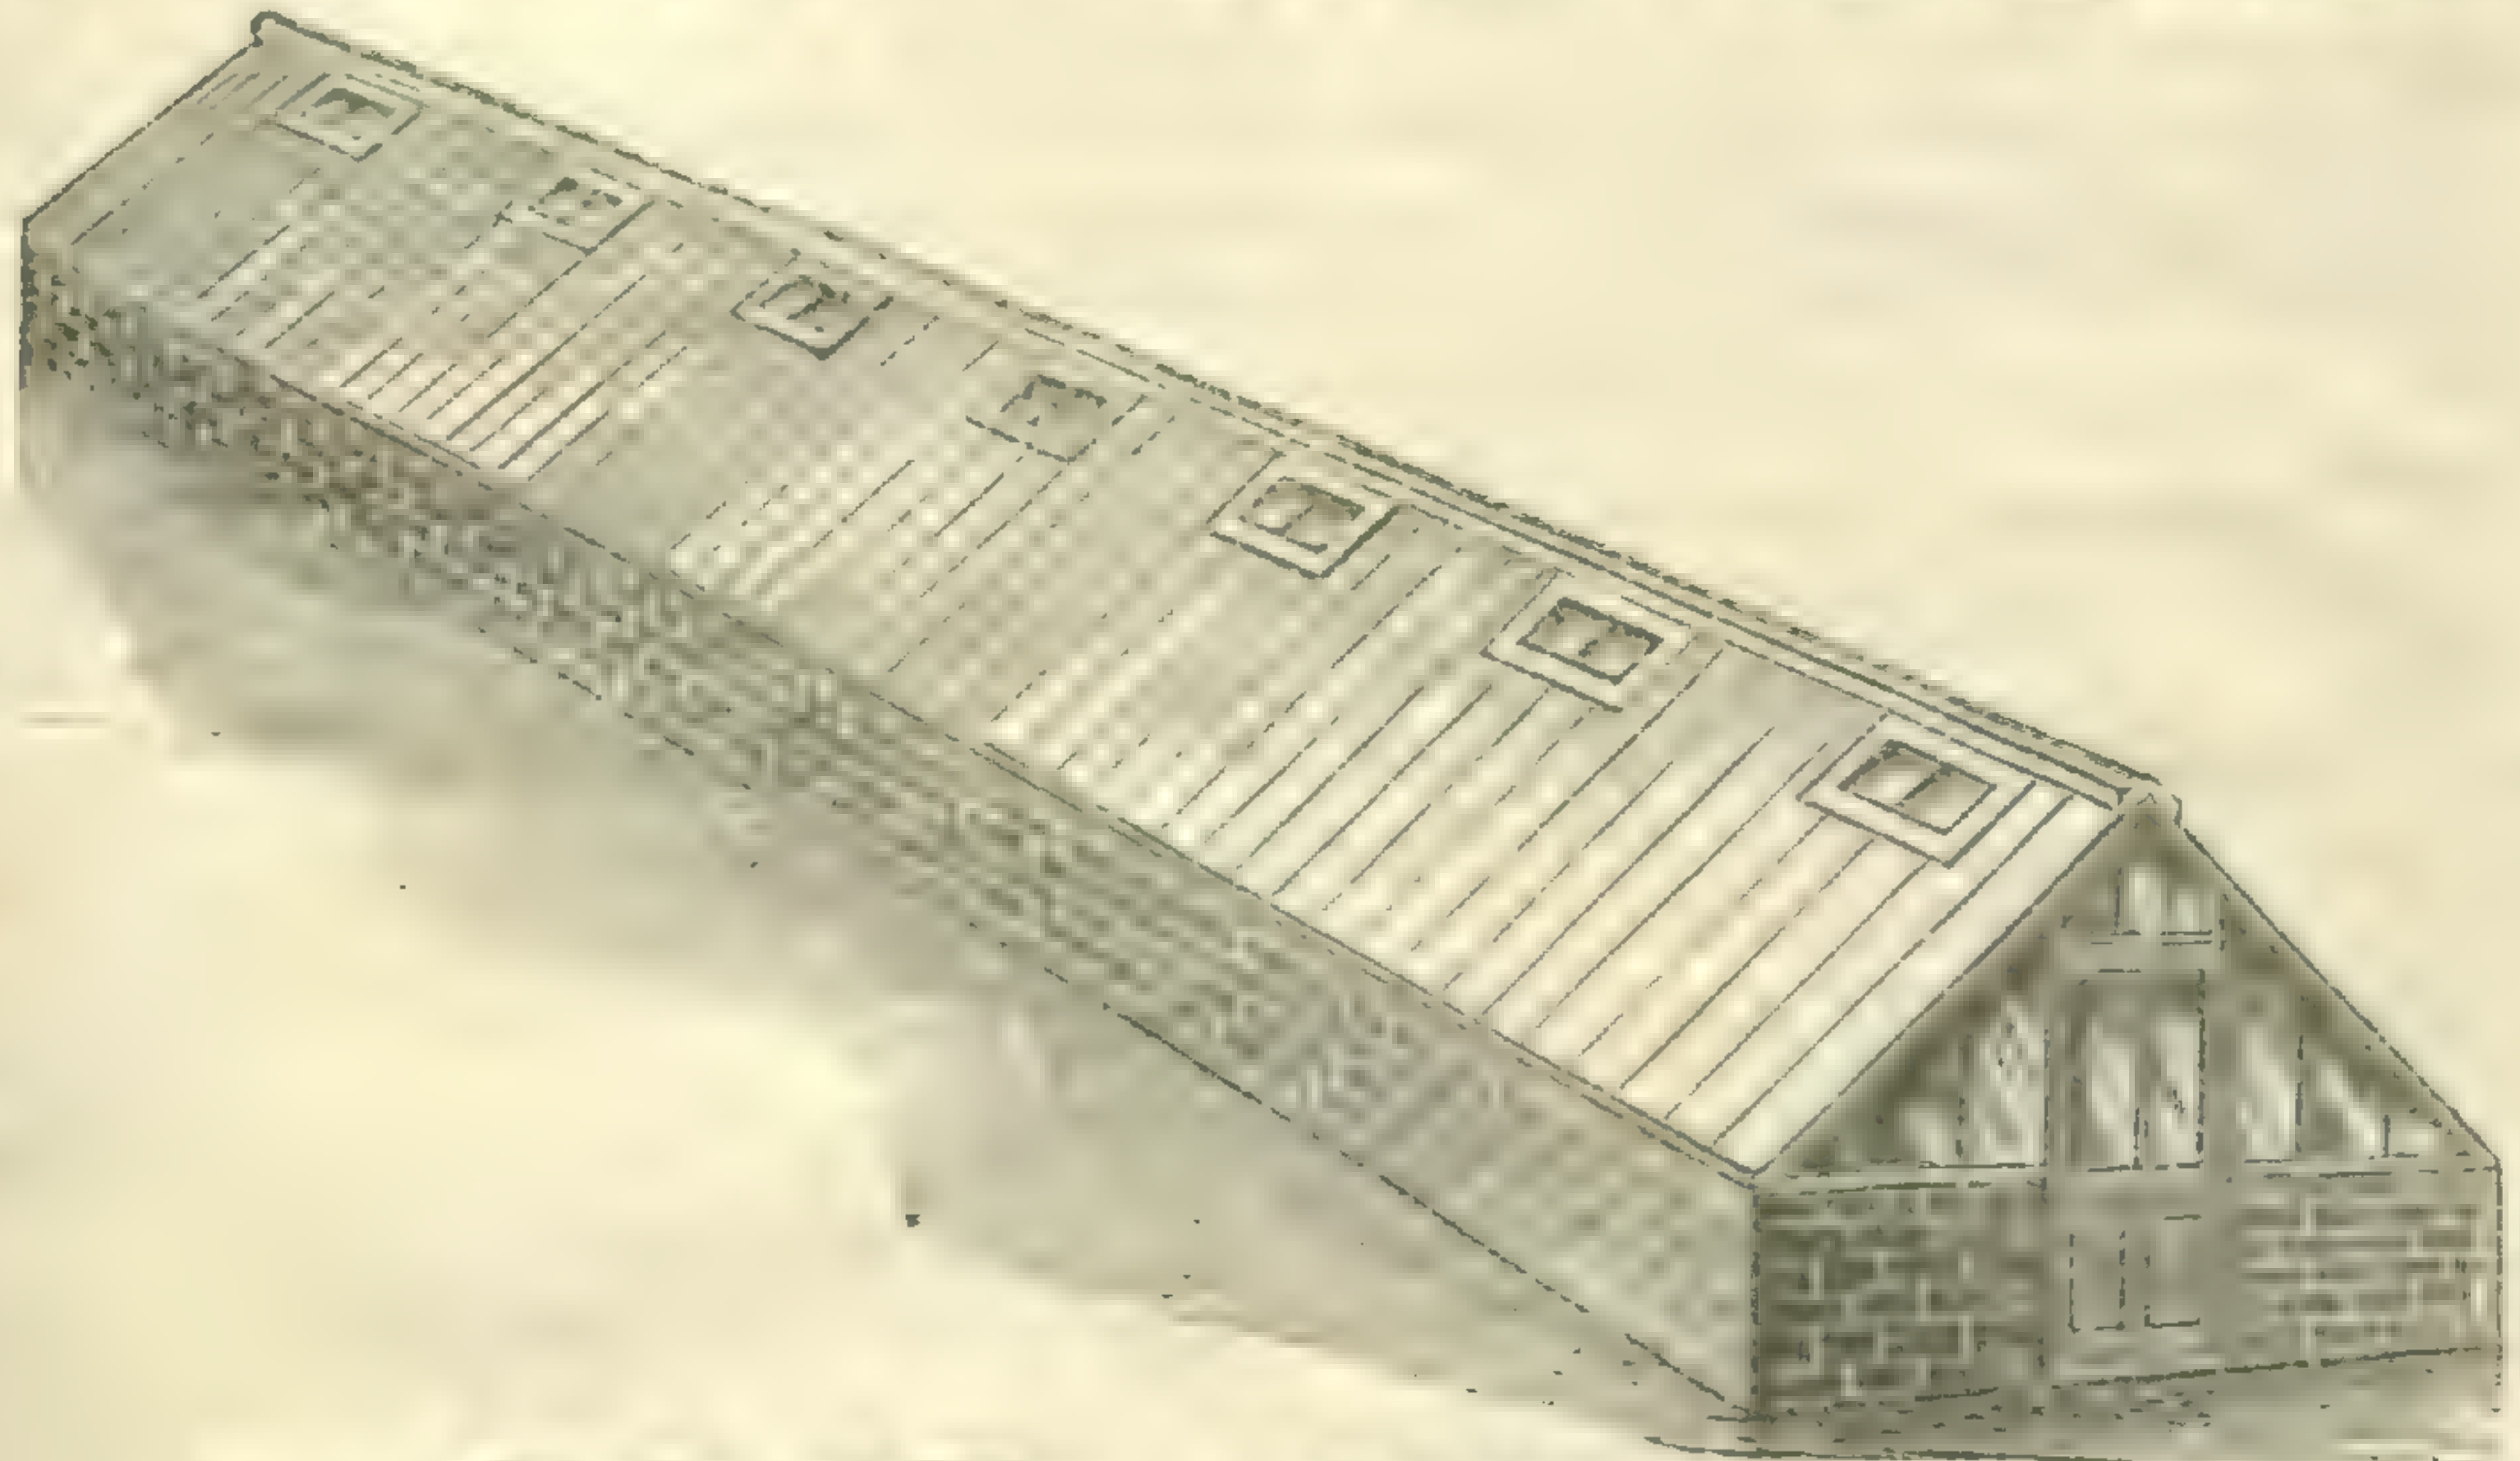
Starting Climbers into Growth.—E. C. L., Lichfield: Both Clerodendrom Thomsonæ (Balfouri) and Bouganvillea glabra may be started into growth at once, and unless the flowers are needed very late there is no need to retard the plants after this date. Bring them into growth gradually, giving more heat and moisture as growth advances. Both these plants will succeed in a lower temperature than is generally given them; in an intermediate house the colour of the bracts is very fine. Combretum purpureum should be placed in a temperature of from 60 to 70 degrees; very little water is needed at first. As the roots work freely it will be necessary to consider whether potting is needed, if not give a good top-dressing after removing the loose top-soil. Raise the temperature gradually, for when in full growth this species luxuriates in plenty of heat and atmospheric moisture, with shade from very bright sunshine. No patent manure will produce colour in crotons; the beautiful coloration is obtained by exposure to sunlight, for crotons only want a light shading during the hottest part of our hottest days. To secure the best results it is found advisable to use either Clay's or Thomson's manure for an occasional top-dressing, as these enable one to grow a perfect plant in a small pot and thus render it more adapted for house decoration.

Chrysanthemums in Scotland.—N. S., Inverness-shire: It is difficult to advise you exactly when to "stop" chrysanthemums with a view to securing the blooms in their best condition at the end of November, because practical experience in your northern climate is the only true teacher of the dates that are most suitable for these operations. If you will adopt the accompanying suggestions this year and carefully note results, whether the blooms are too early or too late, then another season, with these dates as a base, you can vary the timing of your blooms according to experience, and so in working on carefully defined lines you will soon arrive at the correct method. Probably buds "taken" later than August 20 in your locality will not develop good blooms, and it may be advisable for you to house your plants early in September to obtain the best results. Your list includes many sorts scarcely worth growing, and in place of those marked out you should substitute Phœbus, Eva Knowles, Mons. Chenon de Leché, Elsie Teichman, Lady Ridgeway, Lady Byron, Mrs. Palmer, Pride of Madford, Oceana, Thos. Wilkins, Lady Hanham, Mdlle. de Galbert, Mrs. Lewis, Mons. C. Molin, Yellow Madame Carnot, Mrs. Weeks, and Dorothy Seward. You will most likely get the buds of these in good time without stopping, only, the two last-named should be grown straight away from the cuttings and the first bud "taken," which means that you can only have one bloom on each plant, though three plants may be grown in one pot. The Yellow Madame Carnot should be treated like the white variety. Doubtless you have retained a duplicate list and will know which varieties have been rejected. For the benefit of yourself and others in the north we give the following. Natural bud: Viviand Morel, Chas. Davis, Mdlle. Thérèse Rey, Louise, G. C. Schwabe, Mons. Panckoucke, Graphic, Commandant Blusset, Australian Gold, Edith Tabor, Mutual Friend, Wm. Seward, Simplicity, Van den Heed, Richard Dean, Ava-

THE
Cheap Wood Company
SUPPLY
PREPARED MATERIALS FOR
100 FEET LONG. GREENHOUSE 12 FEET WIDE.
PREPARED FROM YELLOW DEAL, NOT FITTED.

SPECIFICATION AS FOLLOWS,
viz.:—
106 feet 1½ × 6 Ridge.
102 ,, 1¼ ,, 4 Capping.
230 ,, 3 ,, 4 Plates.
205 ,, ¾ ,, 3 Drip.
60 ,, Ventilator Seat.
35 ,, 1½ × 2½ Bars for Ends.

SPECIFICATION AS FOLLOWS,
viz.:
4 Pieces 8 ft. 2½ × 3 End Rafters.
14 ,, 6½ ft. 1½ ,, 3 Bars.
102 ,, 8 ,, 1½ ,, 3 ,,
14 Top Ventilators 2 ft. × 3 ft. 10 in.
1 Door 6 ft. × 2 ft. 6 in., Bead and Butt Top for Glass.
Door Frame 3 × 3.



At £8 17s. 6d. for Wood only.

THE CHEAP WOOD CO. are not merely Horticultural Builders. They are large importers of Timber, and have large stocks from which to select what is best suited for this particular branch of work. Such selected timber will be found much stronger and more lasting than a lot which is now sold and sent out with priming, covering a mass of sap, which will turn into rot and make the structure valueless in a very short time.

Customers ordering the above materials may rely upon receiving thoroughly sound timber—well prepared—and orders are executed with reasonable despatch.

All other kinds of Horticultural Work quoted for, also **Glass, Putty, Paint, Boilers, Pipes, &c.**

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

H. H. H., Wadhurst: The fronds sent were not fertile, but the large specimens enabled us to identify the species with some degree of certainty. 1, Dicksonia antarctica; 2, Cibotium Sheedei; 3, Lomaria gibba; 4, Asplenium bulbiferum, a very strong form.

M. E., Widcombe: 1, Hibbertia dentata; 2, Sparmannia africana; 3, Eriostemon buxifolium; 4, Oncidium incurvum; 5, Cypripedium villosum; 6, Linum trigynum.

Names of Fruits.—We are pleased to assist our readers as far as it is possible to do so in naming fruits, but it is absolutely necessary that they should send us good specimens carefully packed, as it is only when characteristic examples reach us in perfect condition that we are able to determine their names. We are compelled to insist on the observance of this rule, as so many specimens now reach us. We cannot undertake to name more than six varieties at one time; and both apples and pears should be sent when approaching maturity, but before they are fully ripe, that we may have the assistance of their distinctive colours in determining their identity.

J. V., Wotton: We hope to reply in our next issue.

Communications Received.—R. D.—J. W. M.—W. M.—W. H. L.—G. S.—A. M.—J. C. T.—W. E. B.—R. W.—H. C.—J. L.—G. W.—M. S.—S. K.—W. W.—C. T. D.—W. A. H.—H. H.—S. H. L.—H. H. H.—J. G. C.—G. V.

Eureka Weed Killer.—The untidy appearance of garden paths upon which weeds have been permitted to grow unchecked is an eyesore to every gardener, and it is claimed for the "Eureka" Weed Killer that such a condition of things need exist no longer. This preparation, which enjoys an extensive sale, and has been freely used by the R.H.S. at Chiswick, has been certified by the secretary as to its utility and effectiveness. Its occasional use would undoubtedly result in an appreciable saving of precious time and tiring operations. The proprietors are Messrs. Tomlinson and Hayward, of Lincoln.

A GREAT INJUSTICE is very often done because some self-assertive people imagine it is next to impossible to make an error. Shakespeare must have made an analytical study of the human heart before he uttered those warning words, "Man know thyself, then others learn to know." This is a lesson we should all try and perfect ourselves in, and when this has been done we have to face the significant fact that unless we cultivate good health, prosperity, and happiness cannot abide with us. Holloway's Pills will aid us to do this. The most eminent medical men agree that for the preservation of good health and cure of disease there is nothing to equal them.—[ADVT.]

NEW INVENTIONS.

New X L All Fumigator.—We understand that the success [illegible] the X L All Fumigator and Insecticide has led the patentee, Mr. G. H. [illegible] of 124, Southwark Street, S.E., to introduce a smaller apparatus, adapted for [illegible] in houses of very limited area, and this is eminently suitable for the [illegible] amateurs. The apparatus includes wax burner and a quantity of the [illegible] which has secured so much encomium. This useful appliance, which [illegible] thorough fumigation up to five hundred feet super at a cost of one shilling, is [illegible] within the means of everyone who desires to keep their plants free from insect [illegible]

New Plant Label.—A really capital plant label has just been invented [illegible] Mr. C. E. West, of the Leeds Orchid Company, Roundhay, Leeds. It [illegible] of a white disc, made of an imperishable material in which celluloid is [illegible] but with a slightly rough surface, so that writing upon it, even with an [illegible] pencil, is quite distinct. This is suspended from a shank of copper wire, [illegible] enough for its stem to be pressed into any character of soil or compost, rendering it useful for orchids and indeed for any class of pot plants. Moreover the flexibility of the wire admits of its being bent if required, so that it can be used for affixing to plant stems with equal facility. The label is reversible, and it has the additional advantage of being thoroughly waterproof. It will probably prove a gardener's desideratum.

The Handy Grass-edge Cutter is the name given to an improved form of edge-cutting implement that is being manufactured by Messrs. Thomas Green and Sons, of Leeds. The trimmer used is of star-like shape, which affords practically a continuous cut, clean and evenly regulated. A further improvement has been effected by a resetting of the angle at which the handle is placed, as the result of much experimental trial. Thus the direction of thrust is now dead upon the cutting point, rendering the work of trimming verges and lawn edges a simple and easy operation, and affording a considerable saving in time as compared with the older device of cutting by shears. Messrs. Green and Sons' lawn mowers are very well known, but it may be added that the result of frequent improvements in these garden necessities is seen in the introduction of springs whereby the larger sizes have been rendered still more efficient and workable, while the light running mowers of the "Monarch" class have made considerable advance in construction and favour.

Peach Trees Shedding Flower Buds.—This defect appears to have been unusually common this season, and is so widely spread that any excuse of a merely local kind furnishes no satisfactory explanation. Generally the failing is found most common on certain early varieties, but this season home as well as American varieties have suffered. Fogs are not to be charged with the evil, but they doubtless have been contributory to intensifying the evil. Even the common reason given, dryness of roots and borders, does not satisfy in every case, because the borders are not dry, yet this again is no doubt largely a contributory cause. The chief one seems to be found in the variation of temperature recently felt, when a few very warm days forced bud nutriment, and a few later cold dull days checked action, and this disturbing influence, when warmth again ensued, led to the falling of the buds. It is, indeed, difficult to find reasons that explain a general defect, yet found under such diverse conditions under glass.—A. D.

THE PRUNING OF ROSES.

THE article in your last week's number by Mr. Fish on pruning roses is very interesting, and should be widely read by amateurs. In mentioning amateurs, I do not allude to our exhibiting amateurs, who, of course, are thoroughly *au courant* as to pruning, but more especially to those who have small rose gardens, and may by this extraordinary season be induced to cut back their plants now. In walking round the suburbs of Oxford, I found that many plants are to be seen already carefully cut back, the latent eyes consequently starting into growth, just as if it was April instead of being February, and essentially a winter month.

There is plenty of time yet to have wintry weather and skating. Only about five years back, we had some splendid skating on the Cherwell at Oxford, 20 degrees of frost, and a bright sun, too, in the daytime, just to finish off entirely what the frost had passed over. This happened in March. Memories of such frosts are quite sufficient to make rose-growers careful, and to the many letters lately received on the subject our advice has been, "Bide a' wee."

There is nothing so likely to give satisfaction as the eye which starts late and then grows quickly. Early pruning does not mean early blooming, by a long way. It is very curious to note how the plants have fared along the south walls. Varieties such as Comtesse de Nadaillac, The Bride, Madame de Watteville, Innocente Pirola, Golden Gate, and others nearly always make a lot of late growth. These we generally cover up lightly with the haulm of cabbage seed. This is a very nice material; in fact, the best for protection. It is not put on too thickly, but just lightly tied round the heads (the ends or tips of the plants are not covered), and in many cases the rose wood may be seen through the covering lower down. We have not taken any of this off yet (March 3), but looking into the heads of some this week find that the thick, hard wood is perfectly dormant, hardly a started eye anywhere, all the growth having gone to the tips, where they are exposed to the light and sun. So that, far from starting pruning, the winter covering is still on, and beneficially. This is as it should be, for tea-roses are sure to come early enough, the plants being pruned when the winter is quite over. But our other hardy varieties which do not require covering! These are a sight to see. Etoile de Lyon, Souvenir de S. A. Prince, Marie Van Houtte, F. Kruger, Alba Rosea, &c., have shoots two, three, and four inches long, some plants shooting out from the collar; they have not even lost their last summer's foliage, and will be bearing flowers in a week or two.

It would be very interesting now if rose-growers would write from different centres and compare notes as to protection, the state of the trees at present, &c. Have some already cut blooms in the south? I should not be at all surprised to hear of this.

But what is, perhaps, a more serious question for exhibitors, "Will our plants throw such fine blooms this year?" having had practically no rest whatever! We had blooms of Madame Lambard in December; this variety especially has been "a-growing," and one might almost say "a-blowing," now for nearly ten months straight off the reel. Roses this autumn have certainly done their best to outvie the mums. At several chrysanthemum shows we have been able to show groups of cut roses which have been very favourably noticed by visitors and the press. I fear I am wandering from my subject, but my last words shall be, "Do not be in any hurry to prune."

Oxford.

ALFRED E. PRINCE

PREPARING EARLY POTATO SETS.

YOUR correspondent "Lux" takes exception to my remarks on the preparation o seed potatos for planting, and suggests that possibly I have been napping, for he says that the "Luxian" sets have been on their ends for weeks. Luxian, indeed! what variety is this? I grow about sixty sorts annually, but have never heard of this before, and should be thankful if my friend would send me a few for trial. He then goes on to say they will remain there until wanted for planting. As I usually plant about the first week in April, I hope he will favour me with a few of this superb sample. I guess, however, they are like those of the Lancashire farmer, who could not cut one of his for a peck if any one would give him the world! Doubtless, however, "Lux" is a master in the art of potato culture, as he appears to be in everything else appertaining to horticulture. All, however, I fear, have not the same convenience for storing potatos as he appears to have; neither, I am afraid, are some of us possessed with his superior knowledge of their requirements. For the information of "Lux," I may state that the whole of our early sets have been placed on their ends ever since last August, and have been exposed to the light the whole time. Seeing that I advocated the preparing the sets of early varieties in this manner for a very long period it is possible for me to have some slight knowledge of the subject, and therefore I may tell him that medium-sized sets are by far the best. What would be considered medium-sized tubers in one variety would be small in another. For instance, a set of Ashleaf two ounces in weight would be considered large. The true test would be to settle the dispute about the size of sets, for anyone who cares to take the trouble to plant rows, say, ten yards in length, with tubers varying in weight from half-an ounce to those of a pound each, he will then see the result for himself. This I have done, and proved beyond doubt that medium-sized sets are the best, having grown the heaviest crop ever produced in England. The quantity, however, produced from a certain weight of seed is no test of the cropping capabilities of any variety, but the amount per acre. It is quite possible to grow a couple of hundredweights, or even more, from a pound of seed, but to grow between thirty and forty tons per acre is another thing entirely. In the one case the sets could be started early, and cuttings taken from them to an almost unlimited extent, while in the other more would depend on the quality of the sets and their after-management than the number obtained.

Had "Lux" been a practical man, he would have known that but few gardeners are possessed with accommodation for placing the sets on their ends until the winter is half over; neither is it actually necessary to do so, unless the tubers have commenced to grow. If those intended for planting are exposed when dug to the influence of the sun, and afterwards stored in a cool, airy place, very few of them will commence to shoot until the winter is well advanced. I wonder how many are so exposed by those who plant acres? It was formerly the practice to plant early in February, but from experience it has been found that nothing is gained by so doing where there is room to properly prepare the sets, for when planting is deferred until the first week in April, there is not much risk of them being cut down by late spring frosts. I know "Lux" will pardon me for answering him at such length; he is not one of those thin-skinned writers who set their backs up at trifles, but I must ask him to be a little more careful in his reading. I said the sets should by "this" be placed on their ends, not that they should not have been done so sooner; but knowing full well the difficulties gardeners have to contend with in this respect, I reminded them that it was not safe to further defer the operation.

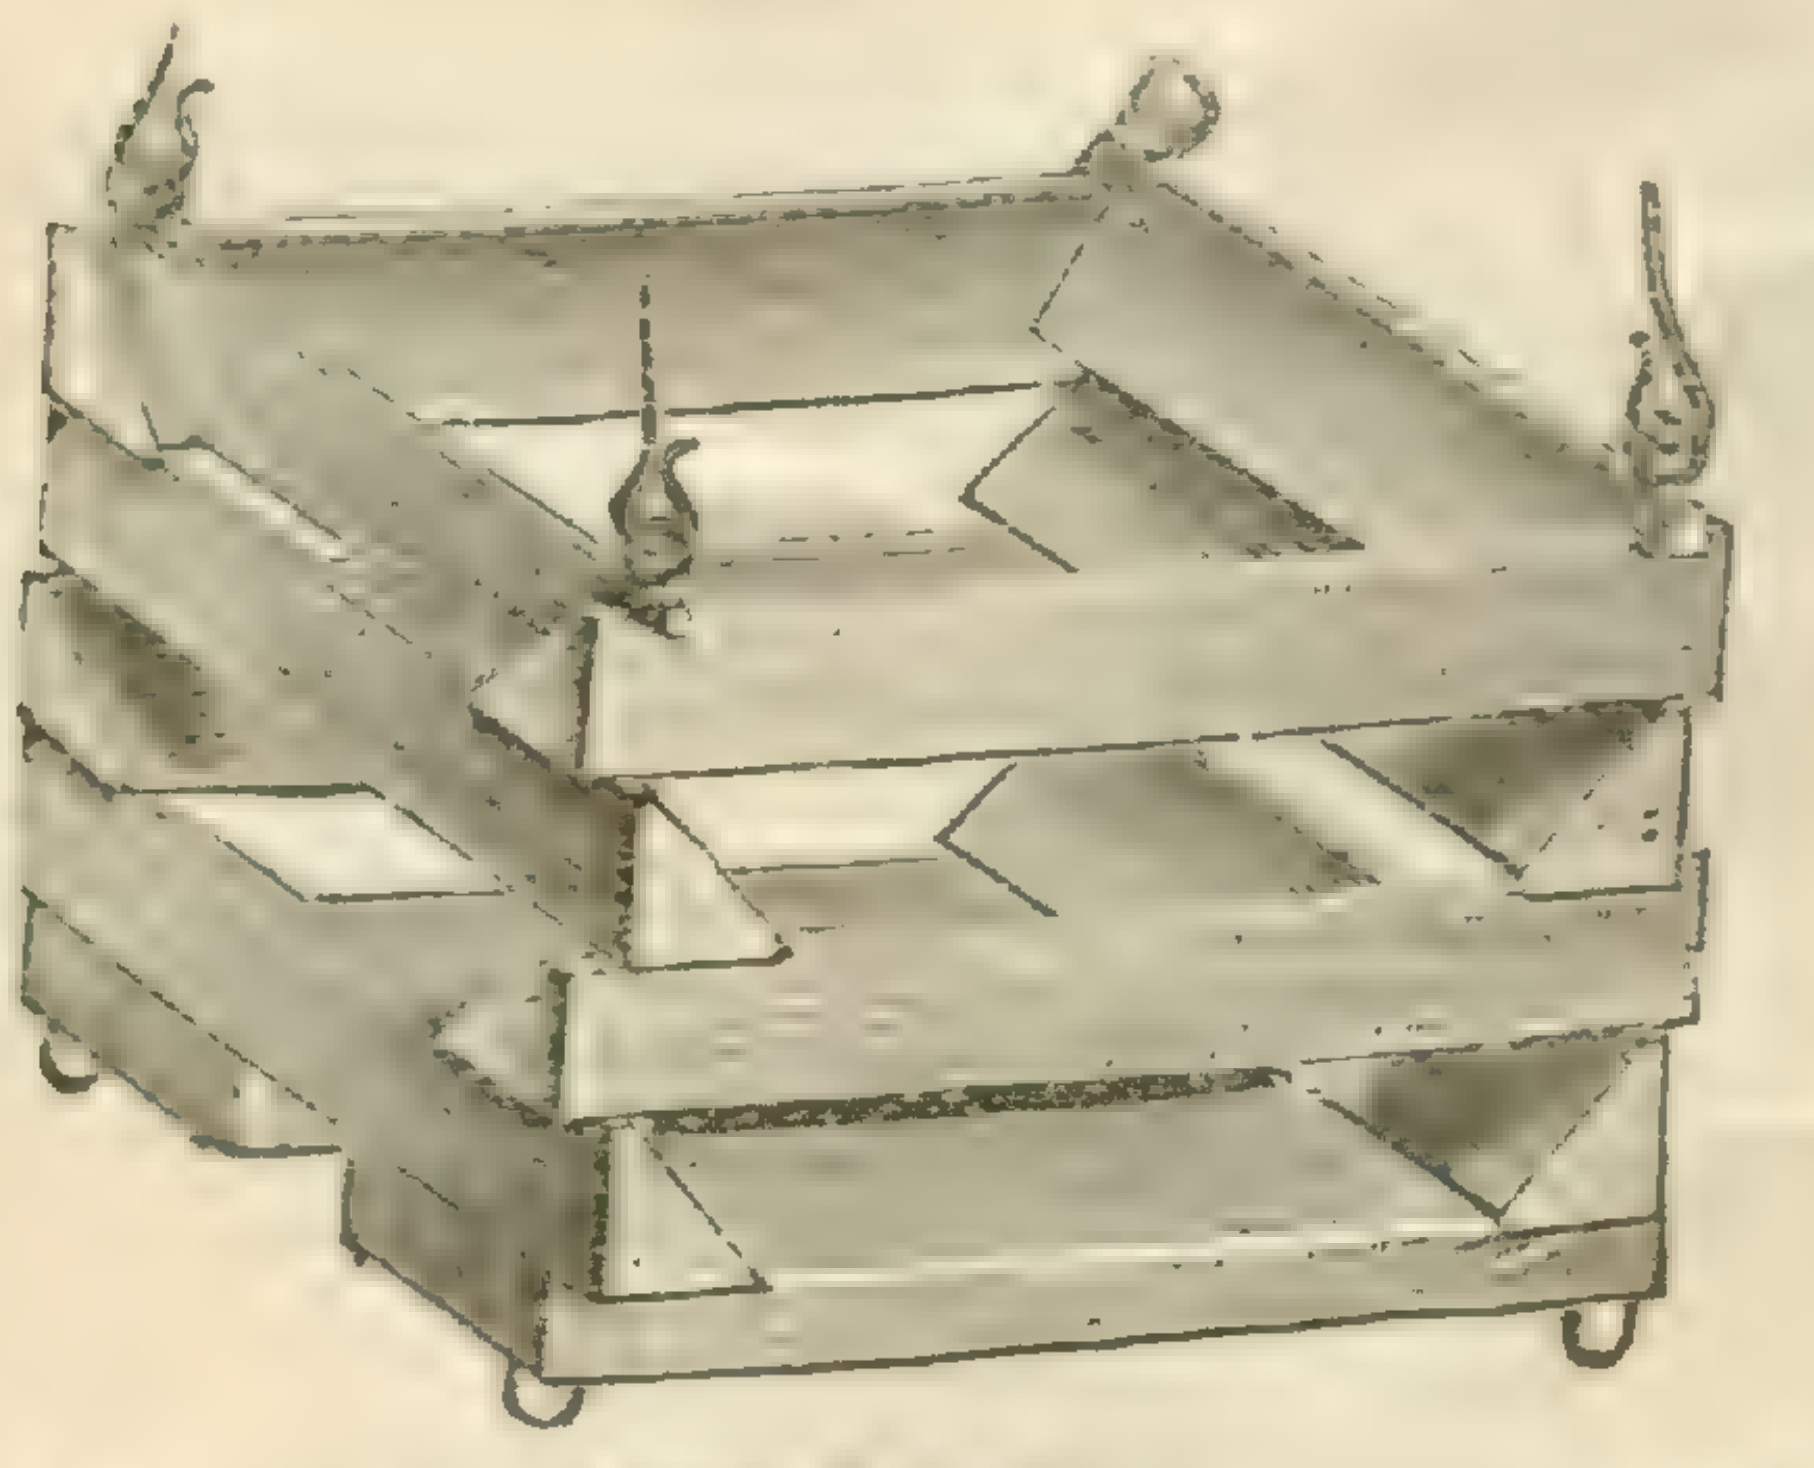
H. C. PRINSEP.

Orchids of every description, from 1s. each. Rare Plants at low prices. Every plant sent on approbation. Correspondence invited. New Catalogue free.—THE LEEDS ORCHID CO., ROUNDHAY, LEEDS.

THE TRIAL.

Harrow-on-the-Hill.
Mr. C. E. West.
Dear Sir,—So far as I can judge, the merits which you claim for the baskets are not without foundation, but I will make experiments and test them.
(Signed) JAMES O'BRIEN.

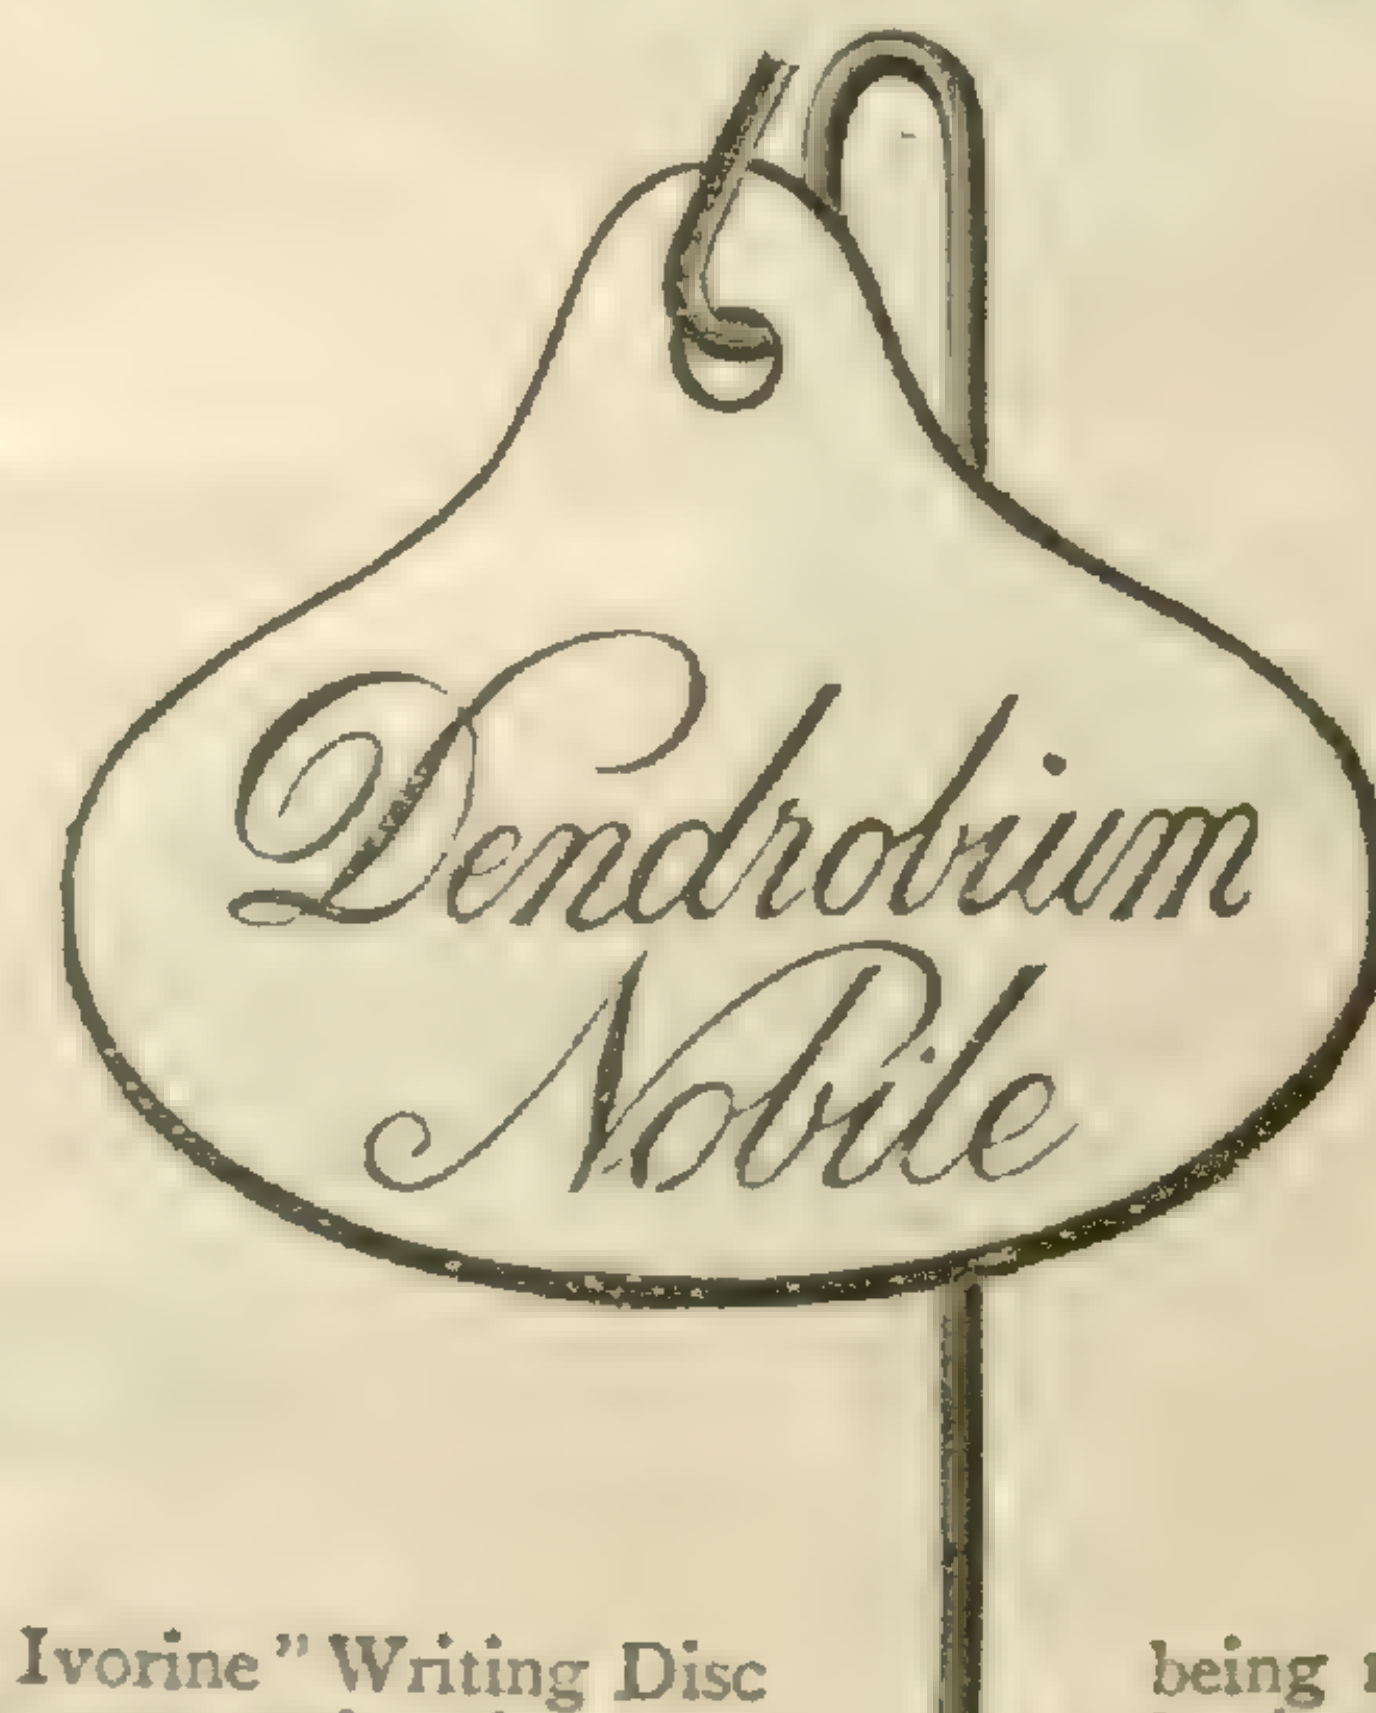
NEW STYLE BASKET.
(West's Patent). *Patent No.* 14,573, *August*, 1895.



5-INCH BASKET.

The West's Patent Teak Baskets, complete with Copper Wire Improved Patent Suspenders, &c., 4 in., 7/-; 5 in., 8/-; 6 in., 9/3; 7 in., 10/3; 8 in., 11/3; 9 in., 12/9; 10 in., 14/6; 11 in., 16/9; 12 in., 18/9; 13 in., 21/6; 14 in., 25/6; 15 in., 28/6 per doz.

The West's Patent
IVORINE PLANT LABELS.



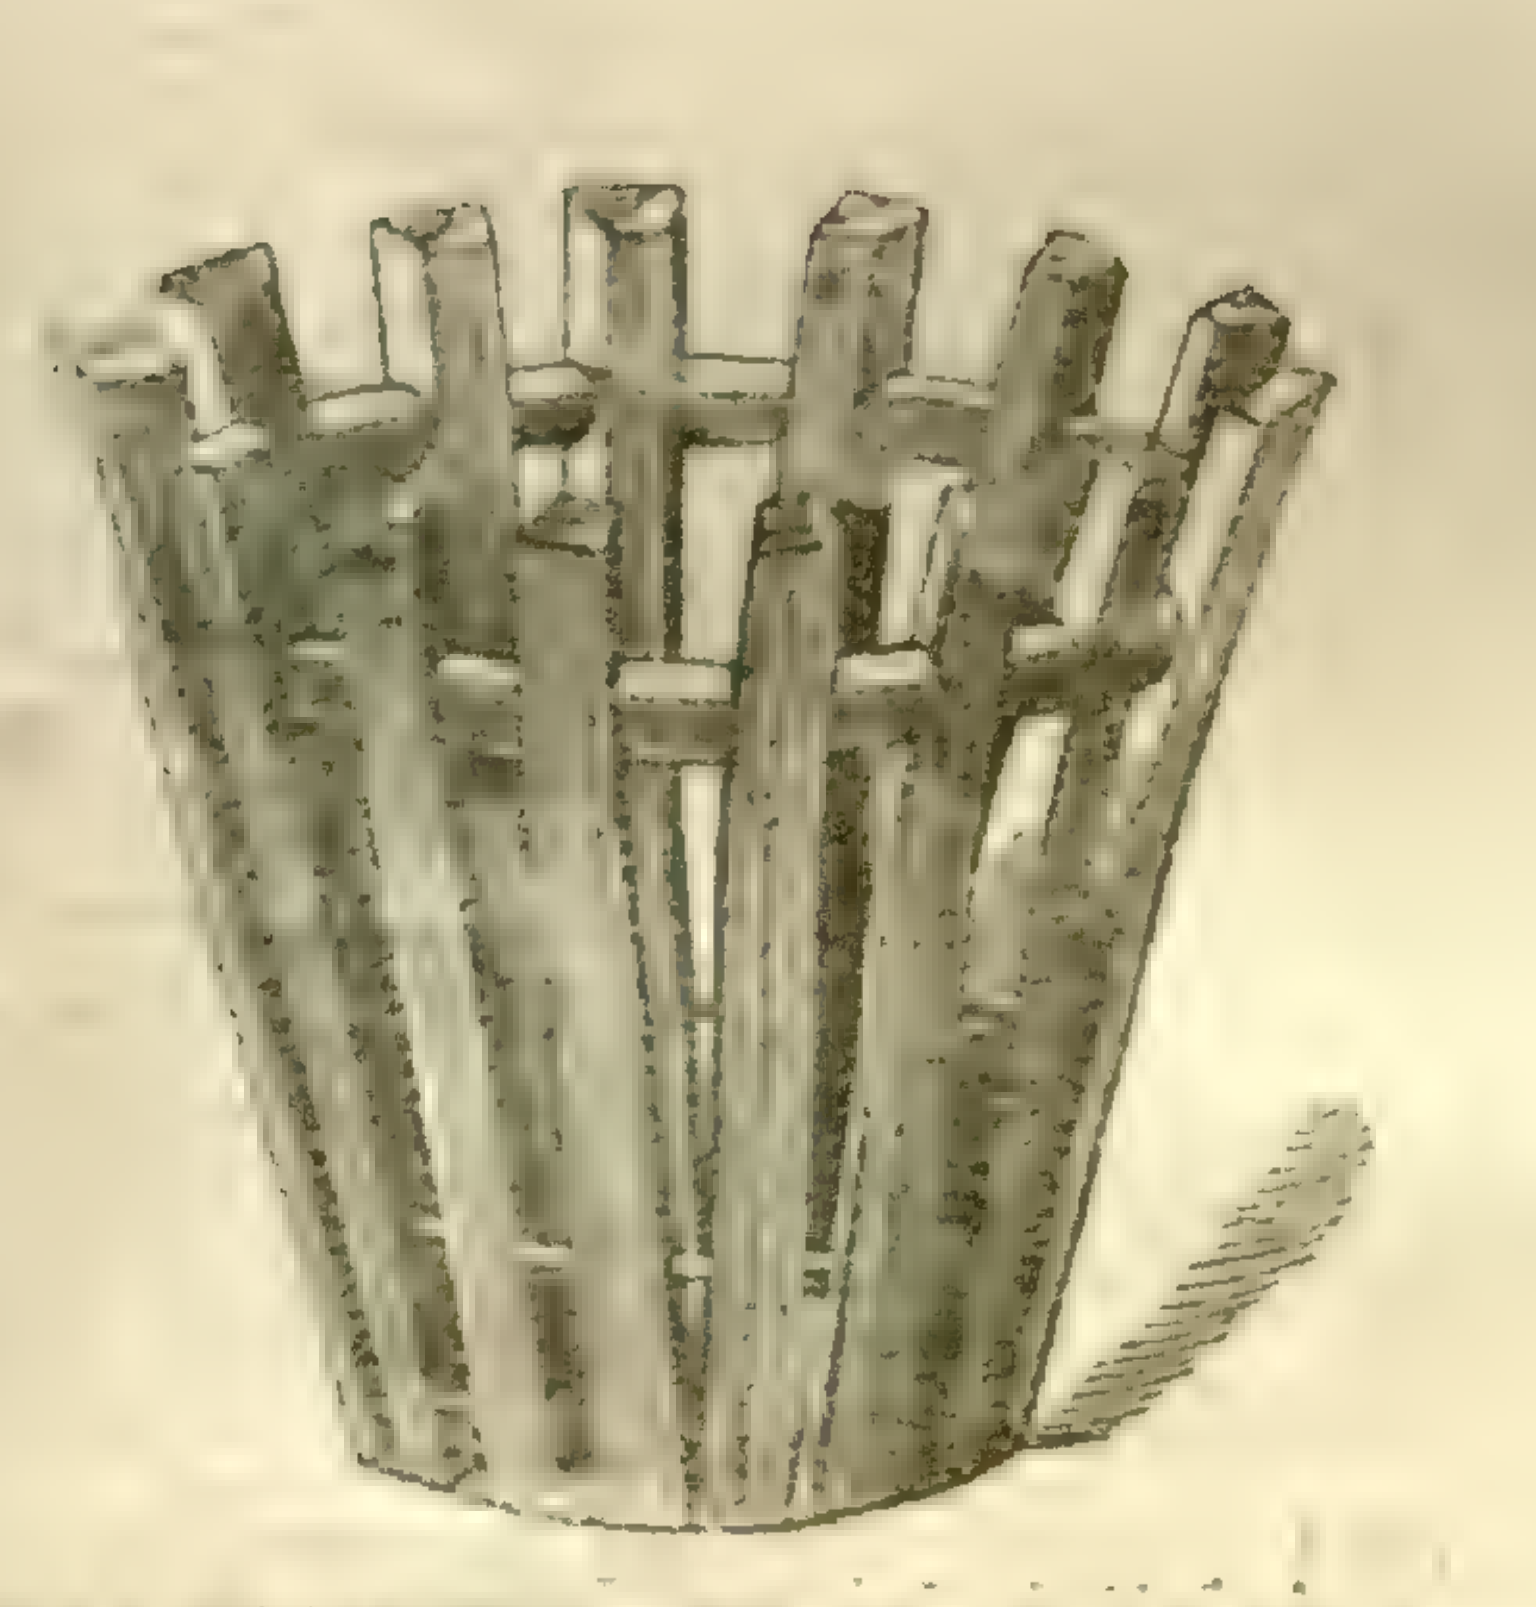
The "Ivorine" Writing Disc being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon by a common lead pencil or pen and ink, it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, and does not become unreadable, as is the case with all painted labels as the paint gets old. The copper wire shank may be used as per the illustration, or it may be bent round the stem of a plant, leaving the name showing in the most readable position.

Samples and Lists of the West's Patent Specialities post free.
Price, **8s.** per gross, Carriage Paid.
Supplied by all Nurserymen, Florists, &c.

FULL SIZE.

THE VERDICT.

Harrow-on-the-Hill.
Mr. C. E. West.
Dear Sir,—Your Orchid Basket has a *great* future, and its best testimonial is given by its imitators.
Yours faithfully,
(Signed) JAMES O'BRIEN, F.R.H.S.



POT-SHAPED TEAK BASKET.

Pot-shaped Teak Baskets, 1½d. per inch; as, for instance, 4 inches deep by 4 inches across, 5/- dozen.

THE LEEDS ORCHID CO., ROUNDHAY, LEEDS.

MARKETS.

Covent Garden.

THE fruit trade is characterised by moderate supplies, a brisk demand, and high prices. Vegetables in fairly good supply, but cut flower trade not very brisk.

FRUIT.—American and Nova Scotian apples, 12s. to 30s. per barrel; Californian Newtowns, 7s. to 9s. per box; English grapes, 1s. 9d. to 3s. per lb.; Belgian, 1s. to 1s. 9d. per lb.; Almeria, 12s. to 20s. per barrel; pineapples, 2s. to 7s. each; bananas, 5s. to 10s. per bunch; French pears, 5s. to 7s. per crate; dates, 10s. 6d. to 12s, 6d. per cwt.; lemons, 8s. to 16s. per case; Canary tomatos, 1s. to 1s. 6d. per tray, 3s. 6d. to 4s. 6d. per case; Valencia oranges, 10s. to 18s.; Denia, 15s. to 25s. per case; Jaffa, 8s. 6d. to 12s. per box.

FLOWERS.—Arums, 2s. to 3s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 6s. to 9s.; Lilium Harrisi, 4s. to 6s.; tea roses, 6d. to 1s.; pink roses, 4s. to 8s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s. 3d.; and tuberoses, 6d. to 9d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; white narciss, 2s. 6d. to 5s.; Roman hyacinth, 4s. to 6s.; daffodils, 5s. to 8s; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 1s. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—English asparagus, 5s. to 7s. per bundle; seakale, 10s. to 12s. per dozen punnets; French endive, 1s. 3d. to 1s. 6d.; lettuce, 1s. to 1s. 3d. per dozen; Brussels sprouts, 1s. 3d. to 1s. 6d. per half sieve; English onions, 5s. 6d. to 7s. per cwt.; Valencia, 7s. to 9s. per case; carrots, 2s. 6d. to 3s. per dozen bunches; celery, 6s. to 12s. per dozen rolls; spinach, 2s. 6d. per bushel; mushrooms, 6s.; eschallots, 2s. per 12 lb.; Italian cauliflowers, 2s. 9d. to 3s. 6d. per hamper; cabbages and savoys, 4s. to 6s.; parsnips, 3s. to 3s. 6d. per tally; forced rhubarb, 1s. 3d. to 1s. 9d. per dozen bundles; Cornish broccoli, 6s. 8s. 6d. per crate; Canary new potatos, 14s. to 18s.; Malta, 16s. to 18s. per cwt.; Algiers, 3d. per lb.

Borough Potato Market.

Supplies are rather large, but trade is quiet. Prices have slight upward tendency.

Dunbars, 110s. to 120s.; Hebrons, 85s. to 100s.; Snowdrops, 80s. to 90s.; Bruce Maincrop and Sutton's Regents, 80s. to 85s.; Reading Giants and Saxons, 80s. per ton; Belgians, 3s. to 3s. 6d.; Germans, 3s. 6d. per bag.

Effects of Earthquakes on Plants.—The published proceedings of the Agri-Horticultural Society of India for the September quarter of 1897 contains the following interesting correspondence. Mr. W. Help wrote on August 14 to the society's secretary: A most remarkable thing has happened to all my Papaya trees since the earthquake. I am sending you some of the fruit to see the condition they are in, and you know what fine ones I had. The fruit I am sending you were the same size as when the earthquake took place on June 12, so that growth in the fruit has been stopped entirely in some remarkable way since then, but not in the plant, which is still growing and flowering in the usual way. It is not one plant only affected, but every one I have. Can it be the earthquake, I wonder, for all plants are very healthy looking? Fruits that have formed outside the influence of the earthquake, a foot or more above where the specimens have been taken from, are growing, and are from three to four times the size of what I send you. The Secretary of the Society adds: "The specimens received were the size of an ordinary duck's egg. In the society's gardens it has been noticed that little or no progress has been made in the growth of Papaya fruit since the earthquake."

THE WEATHER DURING THE WEEK ENDING FEBRUARY 26, 1898.

JOHNSON'S

GARDENER'S DICTIONARY.

A New Edition, Thoroughly Revised and Considerably Enlarged by

C. H. WRIGHT, F.R.M.S.,

AND

D. DEWAR,

CURATOR OF THE GLASGOW BOTANIC GARDEN.

New and Enlarged Edition (1,072 pp.), with numerous Illustrations, demy 8vo., cloth, 9s. net.

"We are glad to see the publishers of this valuable work again in the field with a new edition, thoroughly revised and considerably enlarged. It is without doubt one of the most reliable and important gardening dictionaries that has ever been published; in fact, as a dictionary and guide for gardeners, amateur or professional, its equal is not to be found in horticultural literature . . . forms a marvellous digest of matters horticultural, and a standard work for the guidance of all interested in the art and science of Gardening. It is beautifully printed, and the style in which it is turned out is highly creditable to the eminent publishers."—*The Horticultural Times.*

"The reissue . . . is so considerably enlarged and improved, after a lapse of thirty years since the last revision, as to be practically a new work. From a careful examination . . . we find the revision and the additional matter deserving of all praise. Every gardener, and everyone who [illegible] a garden, or owns one, should possess this book. With the [illegible] features of older works, such as 'Paxton's Dictionary,' it supplies also valuable information with regard to all kinds of gardening operations, culture, insect pests, and other matters of utility."—*Saturday Review.*

"For nearly half a century this Dictionary has been [illegible]sidered one of the leading works of its kind, and for [illegible] reference on horticultural matters cannot be easily eclipsed. The new edition has been ably revised and brought up to date, giving full and accurate descriptions of plants, as well as cultural directions. . . . To amateur gardeners the work is a [illegible] encyclopædia."—*Garden Work.*

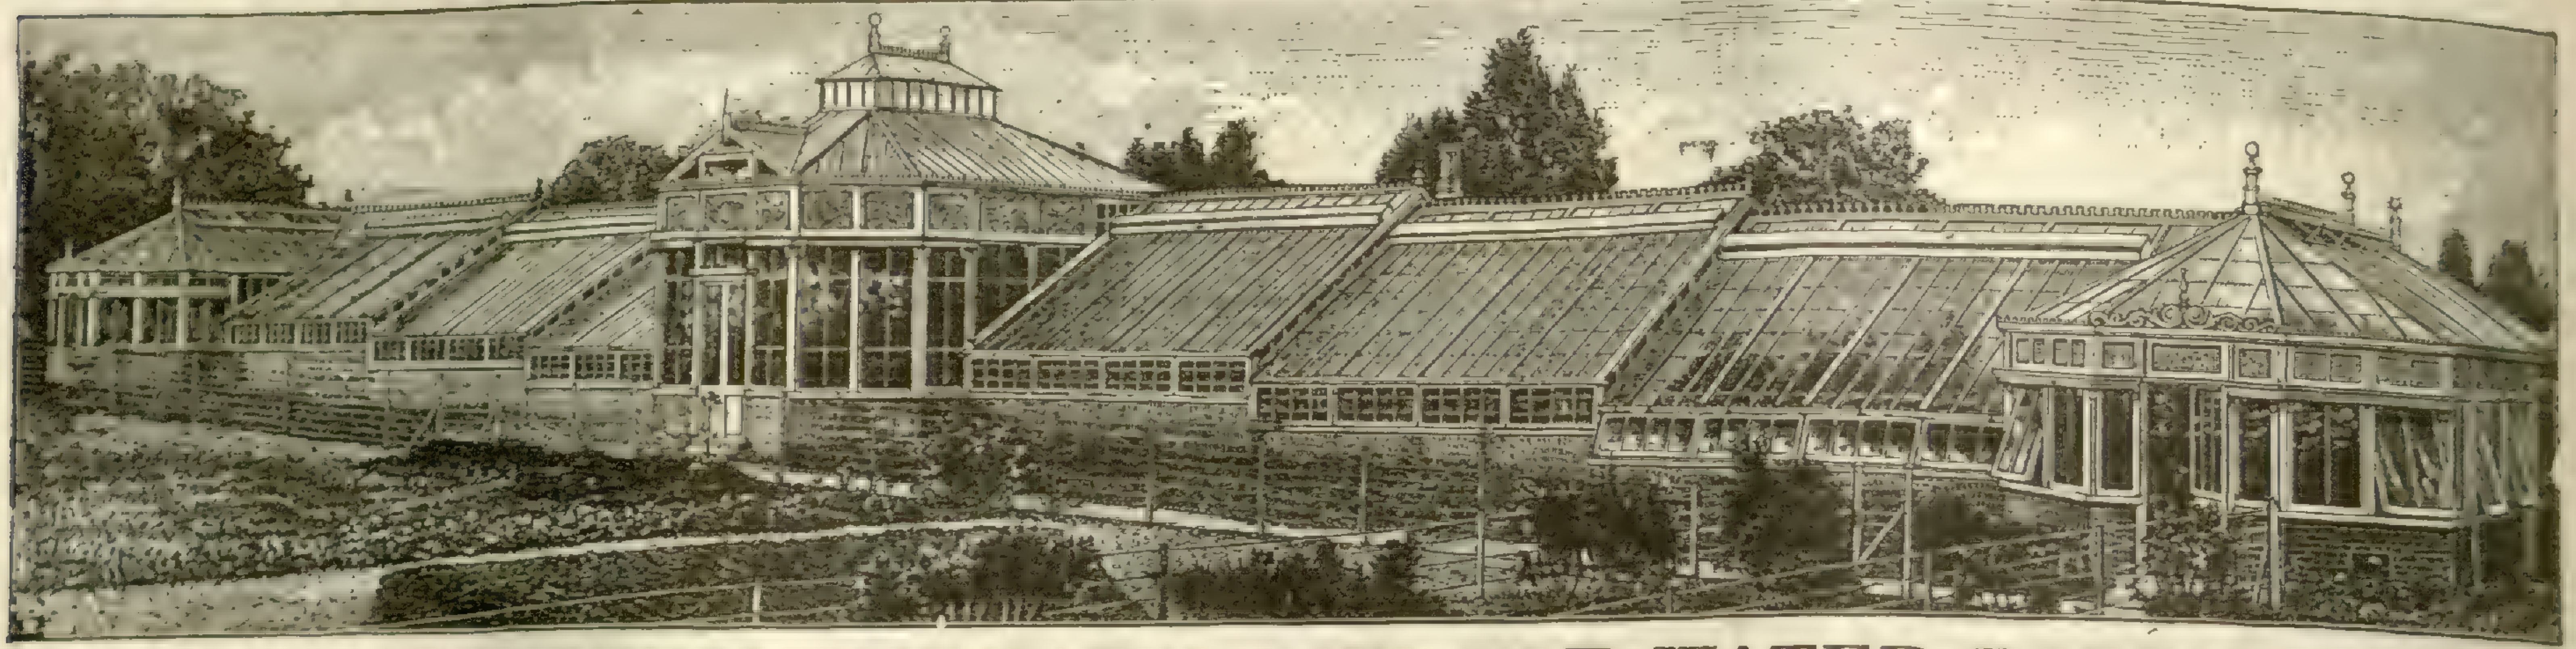
EPPS'S COCOA.

Extract from a Lecture on "Foods and their Values," by Dr. Andrew Wilson, F.R.S.E., &c.—"If any motives—first, of due regard for health, and second, of getting full food-value for money expended—can be said to weigh with us in choosing our foods, then I say that Cocoa (Epps's being the most nutritious) should be made to replace tea and coffee without hesitation. Cocoa is a food; tea and coffee are not foods. This is the whole science of the matter in a nutshell, and he who runs may read the obvious moral of the story."

Crompton and Fawkes, Chelmsford.



HORTICULTURAL BUILDERS AND HOT WATER ENGINEERS.

The Beauty of an English Garden is a

GOOD LAWN

Yet how often one sees poor yellow, moss-grown spaces in place of green, velvety turf. The cause is poverty, constant mowing, and nothing done in the way of restoring the exhausted fertility. Stable manure is an eyesore on a neat Lawn, but

PEARSON'S CHEMICAL MANURE

may be applied with little trouble or expense, and is washed in by the first shower. Will not burn the grass as some compounds do. Apply 2 oz. to square yard any time from now to end of March, 14 lbs., **4s.**; 28 lbs., **7s.**, in Tins. ½ cwt., **12s.**; 1 cwt, **20s.**

TESTIMONIALS FREE.
Half-cwt. and upwards Carriage Paid to any station.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

PRUDENTIAL ASSURANCE COMPANY, LIMITED.

Chief Office—**HOLBORN BARS, LONDON.**

SUMMARY OF THE REPORT PRESENTED AT THE FORTY-NINTH ANNUAL MEETING, HELD ON 3RD MARCH, 1898.

ORDINARY BRANCH.

The number of Policies issued during the year was **65,893,** assuring the sum of **£6,698,755,** and producing a New Annual Premium Income of **£365,996.**

The Premiums received during the year were **£2,774,264,** being an increase of **£231,002** over the year 1896.

The Claims of the year amounted to **£707,643.** The number of deaths was **5,038,** and **656** Endowment Assurances matured.

The number of Policies in force at the end of the year was **497,327.**

INDUSTRIAL BRANCH.

The Premiums received during the year were **£4,793,591,** being an increase of **£214,798.**

The Claims of the year amounted to **£1,823,338.** The number of deaths was **192,359,** and **1,876** Endowed Assurances matured.

The number of Free Policies granted during the year to those Policyholders of five years' standing who desired to discontinue their payments was **60,848,** the number in force being **549,889.** number of Free Policies which became Claims during the year was **10,716.**

The total number of Policies in force at the end of the year was **12,546,132**: their average duration exceeds eight and a quarter years.

The Assets of the Company, in both branches, as shown in the Balance-Sheet, are **£30,438,337,** being an increase of **£3,379,226** over those of 1896. A supplement showing in detail the various investments is published with this report.

Having regard to the growth of the Company, and also with a view to afford relief to the and Secretary, the Directors have made certain rearrangements and alterations in the Chief Office Staff. Messrs. DEWEY, HUGHES, and FISHER will in future be Joint General Managers, and certain duties of administration have been entrusted to a number of senior officials, whose long and intimate acquai with the management has qualified them for promotion. The Directors believe that the traditions of management which have produced such successful results in the past will thus be continued in the future.

Messrs. Deloitte, Dever, Griffiths, and Co. have examined the Securities, and their certificate is appended to the Balance-Sheets.

THOS. C. DEWEY,
WILLIAM HUGHES,
FREDERICK FISHER, } *Joint General Managers.*
W. J. LANCASTER, *Secretary.*

The full Report and Balance-Sheet can be obtained upon application to the Secretary

COMPETITION DEFIED!

OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is logue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

NOTICE.

AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH. IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST. IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

SEED LIST

(Free on Application).

FEATURES.

Alphabetically arranged.
Best sorts, in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.
Many hints and recipes for cooking and serving the various vegetables.
Directions for the storing and forcing of vegetables.
Medicinal qualities of many vegetables and herbs.
Prizes of £5, £3, two of £2, and £1 offered for Photographs of Horticultural Subjects (see page 2 of Catalogue).

THE LIST, containing 93 pages, and a profusion of illustrations, shows (A) **What to Grow**; (B) **How to Grow it**; and (C) **What to Do with it when Grown**; and has been described by an agent on one of the largest estates in England as a BOOK OF REFERENCE.

Another Customer, testifying as to quality, writes: "I should like to add that all the Seeds, &c., purchased from your establishment during the past 14 years have been of the very best quality, and have given great satisfaction."

SHEPPERSON'S NOVELTIES & SPECIALITIES.

— THIRTY-NINTH YEAR OF ADVERTISING. —

The following NOVELTIES and SPECIALITIES having all been grown in a very exposed situation high up on the Derbyshire hills are very hardy, stocky, and healthy, very different to weak seedlings grown in warm favoured situations, which look nice, but very rarely succeed well. All Carriage Free for Cash with order. Descriptive List free.

CHRYSANTHEMUMS (Special Culture), not a collection of old-fashioned sorts, but the cream only of the best English, French, American, and Japanese raisers. Good, well-rooted plants, 12 for 2s., 25 for 3s. 6d., true to name

CARNATIONS, PICOTEES, and CLOVES of the finest-named hardy border varieties, many grand new sorts, strong layers wintered outside, 6 for 2s. 6d., 12 for 4s., 25 (in twelve varieties) for 7s. 6d, unnamed varieties 3s. per doz.

NEW HARDY JAPANESE PRIMULAS.—This class of hardy Primula, which has become so popular either for the outside border or the greenhouse since its introduction, has been greatly improved Six distinct varieties (named) for 2s. 6d.; 12 for 4s.; 25 in 12 varieties for 7s 6d.

CARNATIONS, PICOTEES, and CLOVES.—Will produce 80 per cent of fine double flowers, in self, striped, and spotted varieties, including whites and yellows, all from the finest strains for the borders. 12 for 2s. 6d., 25 for 4s 6d., 50 for 8s.

PRIMULA CASHMERANA.—A really fine spring-flowering plant. Colour, bright mauvy violet. Free bloomer Should be in every garden. Three for 1s. 6d., 6 for 2s. 6d., 12 for 4s.

PHLOXES (Perennials).—Special culture of early and late varieties, the cream only from Downie, Laird and Sons, Kelway, Ware, and other first growers. Six fine varieties for 2s., 12 for 3s., 25 for 5s. 6d., true to name. Strong stools to bloom well.

VIOLAS, during the past few years, have come to the front as few flowers have ever done. They are wanted everywhere, and very few plants produce so fine a display for so little trouble. I have a grand collection, including many new varieties, 12 varieties. 1s. 6d.; 25 for 2s. 6d.; 50, in 25 varieties, for 4s. 6d.; true to name.

PYRETHRUMS (Double and Single)—A grand collection to name, selected from the best English and French raisers as a hardy, free-flowering, easily-grown plant for all purposes. 3 named varieties, 1s. 6d.; 6 for 2s. 6d.; 12 for 4s.; unnamed varieties, 3s. per dozen.

GAILLARDIAS (Perennial Hybrids).—A really grand collection of these most gorgeously marked hardy plants. Colours—Scarlet, crimson, and gold, of different shades; blooms all summer; good strong plants, 6 for 1s. 6d.; 12 for 2s. 6d.; 25 for 4s. 6d.

HOLLYHOCKS.—Warranted all fine double flowers; Chater's and Ware's select strain, strong year-old plants to bloom this summer. 6 varieties, 2s.; 12 for 3s.; 25 for 5s. 6d.

ASTERS (Michaelmas Daisies).—Unrivalled hardy autumn-flowering border plants, for cut flowers, &c. A grand collection of the latest improved colours. Six distinct sorts, 1s. 6d.; 12 for 2s. 6d.; 25, in 12 varieties, 4s. 6d.

CANTERBURY BELLS.—Grand new colours and new forms, double and single, Hose in Hose, Cup and Saucer, and other varieties, 12 plants to bloom well, 1s. 6d.; 25 for 2s. 6d.

GERANIUMS.—Greenhouse varieties. Double and single, by Pearson, and other first-class raisers. Good, well-rooted plants, out of pots, 3s. per dozen; true to name.

DELPHINIUMS.—A splendid lot, raised from 12 varieties of Kelway's. Double and Single, including all shades of Blue, from the very palest to the darkest. Good plants to bloom well, 6 for 2s.; 12 for 3s.; 25 for 5s. 6d.

IRIS GERMANICA.—Rivals of the famed orchid, flowers of peculiar formation, and most exquisitely marked with many bright and distinct colours. Quite hardy. 3 named varieties, 1s. 6d.; 6 for 2s. 6d.; 12 for 4s.; 25, in 12 varieties, for 7s. 6d.

GEUMS.—The new Double Scarlet. A splendid hardy, free blooming plant, fine for cutting, 12 for 1s. 6d.; 25 for 2s. 6d.; 50 for 4s. 6d.

AQUILEGIAS.—A grand collection, including many new colours and new forms; 12 best mixed varieties for 2s.

PENTSTEMONS.—A splendid collection to name; a very showy and useful bedding plant, 3s. per dozen; 25 for 5s. 6d.

PINK (Fimbriata alba major)—Large white fimbriated flowers. A very free bloomer. Should be in every garden. Good plants 2s. per doz.; 6 for 1s. 3d.

CAMPANULA PERSICIFOLIA.—Single White, Double White, Single Blue, and Double Blue. All quite hardy, and unrivalled for border decoration, cut flowers, wreaths, &c. 1 of each for 1s. 6d.; 2 of each for 2s. 6d.

DORONICUMS (Golden Stars or hardy Marguerites).—Three first-class sorts. Harper Crewe, Clusii, and Plantagineum excelsum. 1 of each for 1s. 6d.; 2 of each for 2s 6d.

TOMATO PLANTS.—Two first-class varieties, Challenger and Conference; good plants, 1s. 6d. per doz. Ready in April; order at once.

12 BEAUTIFULLY Spotted or pure White FOXGLOVES for 1s. 6d.; 25 for 2s. 6d.

POLYANTHUS and PRIMROSE (Hybrids).—Splendid mixed colours; finest strain grown. 12 for 1s. 6d.; 25 for 2s. 6d.; 50 for 4s. 6d.

ARMERIA (Thrift).—Pink and white flowers. Plant dwarf and cushion-like. Very useful for rockeries and edging to borders. Quite hardy. 2s. per dozen; 25 for 3s. 6d.

LYCHNIS DIOICA RUBRA.—Double crimson flowers, A useful, neat plant. This has been greatly admired by all who have seen it; three for 1s. 6d.; six for 2s. 6d.

12 HARDY Perennial BORDER PLANTS, named, distinct, and useful for decoration and cutting purposes, 2s.

POTENTILLAS.—A distinct and interesting class of hardy border or rock plants, producing an abundance of flowers of a splendid velvety texture, which are very attractive and ornamental, and for cut flowers they are grand. Three for 1s. 6d., 6 for 2s. 6d., 12 for 4s., true to name.

FUCHSIAS, for Exhibition or Decoration. Order at once for delivery in April. I have a very fine collection, including many new varieties, double and single, light and dark, good healthy plants. 2s. per dozen, true to name.

A MAMMOTH SWEET WILLIAM (Holborn Glory).—This is, without doubt, the largest-flowered Sweet William ever sent out, the florets being much larger than penny pieces. An unequalled speciality for collections of biennials, border, or herbaceous plants. Unaproached for show, exhibition, or staging purposes. 12 for 1s. 6d., 25 for 2s. 6d., good strong plants.

CARNATION.—Margaret. This grand novelty has proved itself to be the most remarkable of all the carnation family. It commences to bloom early in summer and go on till late autumn. It will produce quite 80 per cent. of fine double flowers of a great variety of the most beautiful colours and markings. 12 plants for 2s., 25 for 3s. 6d.

SEEDLING PANSIES (Fancy).—Strong plants to bloom well. 1s. 6d. per dozen, 50 for 5s. 6d.

STRAWBERRY PLANTS.—British Queen, Brown's Wonder, Duke of Edinburgh, President, Sir Joseph Paxton, Sensation, and many other good sorts, strong fruiting crowns. 3s. per 100.

WALLFLOWERS.—Ware's Dwarf Blood-Red and Yellow, also Primrose Dame, good strong plants, all transplanted. 1s. per doz., 6s. per 100.

Patent Single Screw Adjustment.
Made in six sizes, 26 to 48 inches wide.

BENETFINK'S REGISTERED GARDEN ROLLER.

ADVANTAGES.

By making the handle square, lengthening and connecting direct to ends of Roller, the user gains great power of manipulation with half the usual expenditure of force, and risk of breakage.

Size	in.	cwts.	qrs.	lbs.	£	s.	d.
14 by	14	1	2	7	1	6	6

"EUREKA" WEED KILLER,

THE GARDENER'S FRIEND.

Powder or Liquid.

Saves Time, Labour, and Money.

100 square yards of Paths or Drives kept clear of Weeds by applying **2s.** worth of this Weed Killer.

TESTIMONIAL RECENTLY RECEIVED.

ROYAL HORTICULTURAL SOCIETY,
117, VICTORIA STREET, S.W.
Feb. 19th, 1898.

DEAR SIR,
Your "Eureka" Weed Killer gave the greatest satisfaction at our Gardens, and we should be glad of another 5-gallon drum of it.

Yours faithfully,
(Signed) W. WILKS, Secretary, R.H.S.
Vicar of Shirley, Surrey.

TRY "EUREKA" INSECT KILLER!

Clears all Insects without Damage to Plants or Trees.

Price List on application.

BARR'S SEEDS

FINEST SELECTED STRAINS OF TESTED GROWTH

Barr's Ne Plus Ultra French Bean.—A fine forcing variety, very early, and producing an abundance of fine pods. Per quart, 1s. 6d.
Barr's Little Queen Cabbage.—A fine little cabbage of delicate flavour, for spring sowing. Per packet, 1s.; per oz., 2s. 6d.
Barr's Earliest French Shorthorn Carrot.—A favourite for soups, and extremely early; the best variety to sow in frames. Per oz., 10d.
Barr's Early Dwarf Best of All Cauliflower.—Remarkably early, dwarf and compact, with heads as white as snow. Per packet, 1s. 6d. and 2s. 6d.
Barr's Pride of the Market Cucumber.—A specially fine selection, dark green, and of handsome shape; a favourite in Covent Garden Market. Per packet, 1s. 6d.
Barr's "Eureka" Melon.—A grand new scarlet fleshed variety, fruit large and densely netted, flavour delicious; heavy cropper and early; a splendid exhibition variety. Per packet, 1s. 6d. and 2s. 6d.
Barr's Silver Globe Onion.—Handsome for exhibition, of mild flavour, and a good keeper. Per packet, 1s.; per oz., 2s. 6d.
Barr's First of All Radish.—Fine little, short leaved, very early radishes. SCARLET or WHITE. Per oz., 6d.
Barr's Early Ruby Tomato.—Large, solid, bright scarlet fruit, of fine form; an abundant cropper, and best FIRST EARLY Tomato. Per packet, 1s.
Barr's Thickly-fleshed Tomato.—Surpasses all other varieties for depth of fruit, solidity of flesh, high quality, and heavy cropping. Per packet, 1s.
Barr's Seed Guide, containing a full descriptive List of the best vegetables and most beautiful flowers.

NOTES OF THE WEEK.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

RECENT events have created fresh interest in the affairs of the National Chrysanthemum Society and brought us many inquiries having reference to that body. It is not surprising a considerable number of members, who have written to us on the subject, should evince some signs of apprehension as to the future and of a desire for guidance at the present juncture. The position of the society is not, we confess, such as to afford satisfaction to those who are deeply interested in its welfare and in the cause of the flower in whose interest it exists; but from the spirit displayed by the members at the annual meeting, which stands adjourned until the 21st, it is possible to regard the prospects of the society with a spirit of hopefulness. It is not satisfactory that the affairs of the society should have been so managed that at a time when it was enjoying a high degree of popularity it should have to face a deficit, or that the executive should have prepared a programme for the current year that could not have been carried out without having a balance on the wrong side. This is all the more regrettable from the fact that the society is in a position to estimate its annual income and expenditure with a greater degree of exactitude than can those societies who have to depend for a considerable proportion of their income upon money paid for admission by the general public, as this, to some extent, is an unknown quantity. The responsibility for the state of affairs rests upon the executive, but the situation proves to demonstration that the members have not in the past been sufficiently careful in the formation of that body and fully recognised the importance of placing upon the committee members who have had the advantage of business training. It is in the highest sense desirable the several classes of cultivators should be properly represented, but it is not less necessary that members possessing business capacity should have a seat at the committee table; for without due regard to business principles the financial results must be more or less unsatisfactory, and of the truth of this proposition no better proof could be desired than has been afforded by recent events. Had the business side of the committee not been weak there would have been no occasion for the appeal to the members assembled at the annual meeting to place the finances on a satisfactory basis. We would, therefore, strongly advise members to keep this fact in view at the adjourned annual meeting; for with a strengthening of the committee in this direction, and the appointment of a Finance Committee, there should be no great difficulty in maintaining a proper balance between receipts and expenditure, and building up a substantial reserve fund. The question of finance is, to our mind, of paramount importance, and not until that has been disposed of will the members be in a position to profitably discuss the other matters that should have consideration. It will, probably, be found that it will not be possible to reduce the number of exhibitions this year, as contracts have already been entered into; but the members should, with regard to future years, express a decisive opinion on the question of reduction, for a multiplicity of shows necessarily imposes a heavy tax upon the society's funds without bringing credit to the society. There can, indeed, be no doubt that the concentration of the efforts of the society upon a smaller number of exhibitions would be in every way more satisfactory. The question of the place of holding the exhibitions will, it may be assumed, come up for discussion, and having regard to its importance we would suggest that, while we should rejoice to see the exhibitions held in a building wholly devoted to them, no decisive step should be taken in the matter until the several aspects of the question have been fully discussed and a well-devised scheme formulated.

SUCCULENTS.

IT is a very remarkable thing that the great majority of succulent plants—that is, plants with thick fleshy leaves, containing an abundance of moisture within their tissues—are inhabitants of the very driest parts of the earth's surface, where one would imagine the existence of succulents in any form an absolute impossibility. The next curious thing is that if, under the impression that moister treatment would help them, we subject them to it, the greater number would inevitably resent such mistaken kindness by dying offhand. In the splendid collection existing at Kew we find hundreds of species—cacti, euphorbias, agaves, sempervivums, and others—thriving under conditions of drought which give the visitor the idea that the watering cans, so freely used in the adjoining houses, have been absolutely forgotten, while the soil in the pots looks as kindly as so much dry lime rubbish, which indeed it is in many cases. Yet cacti almost as juicy-looking as cucumbers; euphorbias trying their best to look like the cacti, spines and all; agaves with huge leaves of great thickness, and so vigorous in growth that the swelling foliage is squeezed together so as to leave deep imprints of its shape on the adjoining leaves—these and all the rest of the tribe find an adequate supply in some inscrutable fashion, and apparently grow fat on nothing. Here in our humid climate we may conceive that the aerial supply is sufficient; but if we could go to their native habitats we should find them still thriving, though the sun would be much hotter, and for many months in the year the rainfall would be practically nil, while in many cases huge plants may be found rooted in mere rock crevices baked, one would imagine to utter desiccation. Even at home we may see our humble houseleek (*Sempervivum tectorum*) perched on a roof or a stone dyke, and spreading its plump rosettes year after year, despite whole weeks of burning sunshine and lack of water supply. The connection, however, between droughty habitats and thick leaves is so clear, that we must consider the latter as the results of evolution; and if we regard this thickening as the result of ever-recurrent checks upon transpiration, tending to reduce surface area to a minimum, we can see at once the reason, since, weight for weight, the surface or transpiring area of a Cereus giganteus or Agave mexicana is hundreds of times less than that of many thin-leaved plants, such as caladiums, which form the other extreme of foliation in conjunction with the finely dissected fronds of many ferns. In these the leafy tissues, *i.e.*, the transpiring surfaces, are expanded to the utmost, with the result that unless constant and very liberal supplies of water are present, either in the soil or the air, the plants cannot exist. Viewed in this light, we can understand how a euphorbia, one of the self-same family as our common milkweed (or spurge), a soft-tissued plant which exudes a quantity of milky sap when cut, can be evolved in a dry country into huge, spiky leafless green-jointed stems, as cactus-like as possible; and, on the other hand, how a species of cactus, such as the pereskia, can, given more humid conditions, produce leaves proper, and assume the guise of a shrub. Certainly, one of the most interesting features in the leafless cacti and similar plants, is the entire transformation of the stalk into a leaf substitute capable of carrying on the vit functions of foliage; and another is the transformation of the leaves into mere rudimentary spots bearing the prickles, little and big, so characteristic of the tribe.

FLOWER SHOW RULES.

THE laws that govern the proceedings of horticultural societies and the competition for the prizes offered at their annual exhibitions are of a very varied character, and the study of a representative collection of sets of rules as given in the schedule would be interesting, if not particularly profitable. Many are so well prepared that they can be readily understood by members who have not had their minds so trained as to be able to appreciate nice distinctions; some are remarkable for the ingenuity displayed in concealing what those who compiled them desired to convey to exhibitors, while others are so difficult to understand that there is some excuse for a failure to appreciate the object for which they have been drafted. One of the most peculiar rules that has come under our notice for a considerable period is that passed at the recent annual meeting of the Barton-under-Needwood Horticultural Society. The correspondent who sends us the report of the annual meeting states that he regards the rule as "unprecedented," and, although some other term might have been employed, it does very well, for no such rule has yet come under our notice. This rule was "carried almost unanimously," and is "to the effect that if prizes to the value of more than £2 be awarded to any exhibitor, two-thirds of the sum in excess of the £2 shall be withheld by the society." The object of the rule is not strikingly apparent, and therefore it may be useful to state that in introducing the rule it was explained that it had been formulated for the purpose of giving "greater encouragement to the majority of exhibitors," by preventing those who have special advantages "taking the lion's share of the prizes." How the rule will give "greater encouragement" to exhibitors we fail to see, for we should imagine there can be little encouragement in the prospect of having a large proportion of the prize money above a trifling sum withheld. We can fully appreciate the importance of preventing two or three exhibitors taking any considerable number of the prizes, but surely that can be accomplished without depriving those who do not possess exceptional advantages prizes to which, under proper conditions, they would obtain. By limiting the number of classes in which any one exhibitor can compete, the chances of taking first prizes will be more equally distributed; but under the rule to which our attention has been called, the exhibitors having exceptional advantages may take all the first prizes, although not able to receive the whole of the prize money, whilst the less favoured exhibitors have to be content with second prizes, and suffer to the extent represented by the difference between the first and second awards. It is evident it has not occurred to those by whom the rule was framed and passed, that it will affect all classes of exhibitors, and for this reason we have directed prominent attention to the rule as one to be avoided, and suggest that when it is desired to impose a check upon those in a position to take too large a proportion of the prizes, the number of classes in which any one exhibitor may enter should be limited.

IMPORTS OF FRUIT AND VEGETABLES.

THE Board of Trade returns for the past month are far from satisfactory, inasmuch as both the imports and the British and Irish exports are materially reduced in value. The decrease in the value of the imports is £1,474,290, equal to 3·9 per cent., and in the exports of British and Irish products there is a decrease of £222,833, a sum equal to 1·2 per cent. This decline in value is in a large measure due to the lower prices prevailing for many of the commodities as compared with those of the corresponding month of last year. In the case of the imports with which we are more immediately concerned the increases and decreases are about equally balanced, and this section of the returns do not require other than a brief reference to them. Apples again occupy a prominent position among the imports of fruit, but they show a material decline both in qualities and value. The aggregate was 176,736 bushels, of the value of £57,684, or a decrease in quantity of 446,529 bushels, and in value of £112,582. Pears also show, comparatively speaking, a material decrease, the quantities received being 2,782 bushels, of the value of £1,435. Plums, on the other hand, were imported in larger quantities than in February, 1897, and the quantities received amounted to 775 bushels, of the value of £1,750. Of grapes 795 bushels, of the value of £1,518, were imported, and it is interesting to observe that, although there is a decrease of 610 bushels, there is only a difference of £432 in value. Unenumerated fruits continue to increase, and while their value was only £16,867 and £19,237 in the corresponding month of 1896 and 1897 respectively, it was £26,312 last month. Turning to vegetables, we find that there is again an enormous increase in the imports of potatos, these amounting to 532,843 cwt., against 40,796 cwt. in the corresponding month of last year. Germany sent us 216,151 cwt. and France 135,024 cwt., both being large increases. Onions dropped from 552,119 bushels to 362,263 bushels, and the respective values are entered as £51,379 and £69,989. Unenumerated vegetables are returned as of the value of £71,571, which is somewhat higher than in the corresponding month of last year, but less than in 1896.

An Interesting Hybrid, obtained by crossing an azalea with a rhododendron, was exhibited at the recent R.H.S. meeting by Sir Trevor Lawrence, Bart., Burford Lodge, Dorking. We believe that the cross was effected by Mr. Pynaert van Geert. The generic title given is Azaleadendron, and of the two forms shown that named Dr. Masters is the best. This has somewhat campanulate flowers of a pale rosy carmine shade, the upper segment being spotted with brown; the foliage reminds one of that seen on the pontic azaleas. Judging from the appearance of the flowers we think that Prince Camille de Rohan must have been the rhododendron used as one parent. The Floral Committee was equally divided as to the advisability of certifying this hybrid, and if the award had been made it would have been given to mark a distinct break away from ordinary things rather than for any great horticultural merit the plant possessed. A Botanical Certificate might have met the case.

Mr. Charles Baltet, president of the horticultural society of Troyes, has been made a Chevalier of the order of St. Anne of Russia.

Australian Plants Yielding Perfume.—Although the [illegible] colonies are rich in plants yielding delicious perfumes and valuable [illegible] little or nothing has, we are informed by Mr. Plummer, been done, so far, to practically utilise the advantages thus afforded. Systematic flower farming is still in its experimental stages, and there exists an almost untouched field of [illegible] extent at the command of those possessing the necessary capital and [illegible] the manufacture of perfumery and essential oils, coupled with the [illegible] abundance of mutton fat, so largely used in the perfumery trade, at [illegible] prices. In New South Wales all the garden flowers of Europe and Asia, [illegible] those emitting the richest fragrance, are found growing in unsurpassed [illegible], many being obtainable nearly all the year round, their profusion and cheapness proving how easily they are reared. Several of the essential oils obtained from the leaves of native plants are really perfumes, and their chief use is in scenting soaps and other preparations. The quantities used are small, and the plants used are wild. Among the native perfume-yielding plants which remain unutilised are several varieties of acacia, including a few which furnish a scented wood. Acacia Farnesiana, which is largely cultivated in Italy and the south of France, the well-known pomade, called "Cassia," being produced by placing the sweet-scented flowers in melted mutton fat or olive oil, until the latter become impregnated with their odour, grows plentifully in many parts of New South Wales; and another species of acacia, familiarly known as the Golden Wattle, is equally useful as a perfume plant; as is also the Native Laurel, or Mock Orange. Among the plants which yield perfumes are the Native Sassafras, Peppermint, Bloodwood, Blue Gum, Mountain Ash, White Gum, Iron Bark, Woolley Butt, Spotted Gum, Tallowwood, Messmate, Red Gum, Poplar Box, and other species of eucalyptus; Ridge Myrtle, Tea-tree, Native Peppermint, Dog-wood, and Turmeric.

M. H. A. Burberry, who until recently had charge of the orchid collection at Highbury, the residence of the Right Hon. J. Chamberlain, M.P., gave a lecture on "Orchids" before the Beckenham Horticultural Society a few [illegible] ago. Mr. Burberry proved a great attraction, and his lecture was followed by a brisk discussion. Mr. Potter, gardener to H. O. Potter, Esq., staged numerous well-flowered orchids that helped to illustrate the lecturer's remarks.

The United Horticultural Benefit and Provident Society holds its annual meeting at the Caledonian Hotel, Adelphi, on Monday, March 14, at eight p.m. The chair will be taken by Mr. George Wythes, who controls the horticultural department at Syon House, Brentford, the residence of Earl Percy. It is hoped that there will be a large attendance, as, after the usual business, there are several proposed alterations of rules to be considered.

Cinchona in India was the subject for discussion after the usual monthly dinner of the Horticultural Club, held at the Hotel Windsor, on March 8. The discussion was opened by Mr. J. F. Gammie, formerly deputy superintendent of the Government of Bengal Cinchona Plantations.

A Gigantic Rose Show at Frankfurt.—It is proposed to hold a monster rose show at Frankfurt-on-the-Main during the coming season, and so sanguine are the promoters that they anticipate the finest rose exhibition that has ever been held on the Continent. This Rosen-Ausstellung will open early in June, and remain open until the end of September, and, if the weather prove favourable, it may be continued into October. Further particulars can be obtained from the director of the Great Rose Exhibition, Frankfurt-on-Main.

West Indian Sugar.—One of the conclusions arrived at by the Royal West India Commission and published in its report is that if the production of sugar is discontinued or very largely reduced, there is no industry or industries that could completely replace it in such islands as Barbados, Antigua, and St. Kitts, and be profitably carried on, and supply employment for the labouring population. In Jamaica, in Trinidad, in British Guiana, in St. Lucia, in St. Vincent, and, to some extent, in Montserrat and Nevis, the sugar industry may in time be replaced by other industries, but only after the lapse of a considerable period and at the cost of much displacement of labour and consequent suffering. In Dominica the sugar industry is not at the present day of great importance. The Commission thinks it right to add that in all colonies where sugar can be completely, or very largely, replaced by other industries, the colonies in question will be in a much sounder position, both politically and economically, when they have ceased to depend wholly, or to a very great extent, upon the continued prosperity of a single industry. The total or partial extinction of the sugar industry would, in most places, very seriously affect the condition of the labouring classes for the worse, and would largely reduce the revenues of the colonies. Some of the colonies could not provide the necessary cost of administration, including the relief of distressed and necessitous persons, or of the support and repatriation (when necessary) of the East Indian immigrants, without subventions from the mother country.

Brighton Horticultural Society.—The committee of this important society keep the educational aspect of its work constantly in view, and they have as usual, prepared an excellent programme for the current year. The session was opened on February 17 with "A Chat about Chrysanthemums," by Mr. H. J. Jones. The subjects to be discussed at the remaining meetings are as follows: "Garden Roses," by Mr. George Gordon, March 17; "Experiments in the Cultivation of Vegetables," by Mr. F. W. E. Shrivell, April 21; "How [illegible] and Feed," by Mr. T. W. Sanders, May 19; "Notes on the Newer Water [illegible]" by Mr. J. Hudson, June 16; "The Nature and Development of Buds," [illegible] H. Elliott, July 21; "Dahlias," by Mr. R. Dean, August 18; "[illegible] Winter Flowering," by Mr. F. Capp, September 15; "Vegetables for [illegible] *versus* Vegetables for the Table," by Mr. H. C. Prinsep, October 20; "[illegible] Preservation of Fruit," by Mr. A. Kemp, November 17; "Exhibiting Chrysanthemums," by Mr. George Gordon, February 16, 1899. The dates of the [illegible] tions are March 29 and 30, August 23 and 24, November 15 and 16, [illegible] date of the annual meeting, January 19, 1899.

The Beginnings of Plants.—In one of his recent interesting lectures, Professor Ray Lankester showed that the primal difference between plants and animals was based upon what each was able to eat. The organisms which can only eat substances of no lower chemical elaborateness than starches, sugars, and albumens are said to be holozoic; and all the animals belong to this class. Those which can eat oxygen and carbon and nitrogen, and have the power (with the help of chlorophyll and sunlight) of separating oxygen, are called holophytic. But between these two comes the anomalous class—the organisms which have a mouth and eat animal's food, and yet have chlorophyll corpuscles to enable them to get sustenance as the plants get it. These, we say, are saprophytic, and it is among such organisms that we have to search for the point where the animal world and the vegetable kingdom start. There is green plant called the Englena which has a mouth, and yet has the chlorophyll corpuscles which would class it as a plant; and there are among the tiny organisms of the "flagellata," or whip swimmers, several we should class as animals, and yet which have the green corpuscles in their minute structures. This is, therefore, one reason for believing that it was among the "flagellata" that the vegetable kingdom first found its origin. Broadly speaking, said the professor, one might say that if in the beginning a group of "flagellata" joined themselves end to end so as to form a thread, they turned into a plant; whereas if they followed more complex courses and joined together in more elaborate structures and households, they became animals.

At the R.H.S. Gardens, Chiswick, the work of renewal and improvement moves steadily on. The long peach house has been rebuilt, and is now a useful structure, with a higher roof than formerly, thus giving the standard peaches such additional head room as they needed. The wire-tension house, presented some time ago by Messrs. Skinner, Board, and Co., has also been turned into a peach house, a purpose for which it appears eminently adapted. Some borders of sound material have been made up under Mr. Wright's superintendence, so that the half-dozen thrifty peach trees presented by Messrs. H. Lane and Son, Berkhamstead, herein planted should soon make good headway. An interesting orchid, and one that does not flower very freely as a rule, has produced a couple of good spikes in a warm house; this is Dendrobium speciosum, and Mr. Wright considers that the large amount of sunshine it was subjected to last season has caused the specimen to flower this year.

Mr. Peter Barr, the originator of the firm of Barr and Sons, seedsmen and nurserymen, of Covent Garden and Thames Ditton, has, as our readers are aware, resigned the conduct of the business to his sons. This course allows Mr. P. Barr leisure to indulge his desire to travel. Recently he renewed his acquaintance with the highlands of Spain, where formerly he found many new and beautiful daffodils. Now Mr. Barr proposes visiting the United States, Canada, Japan, some parts of China, Australia, New Zealand, and the Cape of Good Hope. We wish Mr. Barr *bon voyage*.

Keeping Apples.—Mr. R. H. Taunton, of Brook Vale, Witton, reports that he has for the second year kept his apples in excellent condition during the winter in clamps. The apples were clamped in the same way as potatos in the autumn when they were gathered, and when the clamp was opened the other day were as fresh and sound as when picked. The varieties were Wyken Pippin, Improved Northern Greening, and Royal Russet.

A Bacterial Fertiliser.—Under the name of "alinit" a new manure has been recently introduced. The discoverer of this material is Herr Caron, of Ellenbach; and alinit in its present form is the outcome of four years' experimental investigations on the bacterial flora of different soils, resulting in the isolation of a particular bacillus, upon the presence of which would appear to depend to an important extent the fertility of certain soils. Caron has, according to *Nature*, already obtained striking results on an experimental scale with crops from soil treated with pure cultures of this bacillus—*Ellenbachensis alpha*, as he has called it. Alinit is sent out as a creamy-yellow powder, of which the nitrogenous constituents have been ascertained to be 2·5 per cent. Its closer investigation has been made the subject of memoirs by Stoklasa, of Prague, and also Messrs. Stutzer and Hartleb. The bacillus is contained in this powder in the form of spores, and on cultivation is found to belong to the well-known aërobic group of bacteria known as the hay bacilli, resembling very closely the Bacillus mycoides so frequently found in soil, and the Bacillus megatherium. It appears to grow easily upon all the usual culture media. Before its precise place amongst bacterial fertilisers can be determined, many more elaborate and carefully conducted experiments must be carried out.

Shirley Poppies appear to be finding much favour in America and a correspondent of [American] *Gardening* writes as follows with reference to the effect they produced in a border along the front of a shrubbery. There were hundreds of blossoms, a labyrinth of bloom and colour. Glowing flowers of dark scarlet satin, thick, smooth and without a wrinkle to mar the shining surface of the rich petals, and in the centre a black maltese cross surmounted by a crown of black stamens; others orange, scarlet, flame, pure red, rosy red, rose, rose pink, shrimp pink, apricot, salmon, salmon pink, blush, flesh coloured, mauve, pearl, and snowy white. Some in plain solid colours, others bordered with white from the merest silver thread to a half-inch band, and white ones tinged on the edges as by a lightly loaded paint brush dragged softly outward on each petal. Some with, others without a black or a white maltese cross in the centre, yet others with the black or white blotch on but two of the four petals. But all wearing a splendid crown of closely massed, dull black or golden stamens in which big bumble bees, all black and gold themselves, seem always to be tumbling. There was nearly as much variety of texture as of colour. Satin of heavy and light quality, several sorts of silk, crepe and tissue paper in various conditions, as smooth, fluted, crinkled, crimped, and creped. The border presented some new feature every day Each morning it was a study and revealed variations from all previous aspects.

A MORNING MIXTURE.

Diluculo surgere saluberrimum est.

We have a little bit of fight in us, we of the GARDENERS' MAGAZINE. When there is anything lively coming on we make no preliminary fuss; we bide our time quietly; but we are there or thereabouts when the scrimmage begins. Our position for the present is "referred back." What will happen subsequently we do not attempt to say, but we are in a position to claim a preliminary victory, and an ultimate one is as safe as —well, from want of a better simile, let us say safe as Lombard Street. That decorous thoroughfare is not what it used to be, if we can believe the foreign gentry who are good enough to supply us with apples and plums, potatos and "unenumerated," but it is not quite on its last legs yet, and is very likely a good deal stronger and a good deal healthier than the foreign gentry thoughtfully suggest.

An individual who has been privileged to read the foregoing, unkindly remarks that it is of a typical "Luxian" nature, because (1) it appropriates credit for what some one else has done (meaning the fighting, I suppose), and (2) nobody can possibly understand what it means. I protest against both charges. Wherever there is a score to boast about it is an accepted thing that every respectable journal shall become like the Revolution Republic—one and indivisible. If there is blame accruing, why then the staff separates itself out, and merely exchanges the coldest of nods in passing on the stairs, which is according to human nature, I believe. As to the matter of ambiguity, there is only one topic of the moment, and that is neither the Zola trial nor the County Council election. Each of these events pales before the fierce blaze of interest aroused by the fight for control of the National Chrysanthemum Society. What, after all, are the puny bubbles of the outside world? Are they not all empty scares? One day it is the Near East and the next the Far East which is troublesome. Then South and West Africa ring the changes. But it all comes to the same thing in the end. The country keeps going and will do so. Sensible men never worry about it, knowing that which ever party is in power it is in safe hands. They pay their taxes and wash the bad taste out of their mouths with the sweet waters of gardening.

I am not, as I have said, going to play the part of prophet; I am only going to comment on current events. The moral of them is plain enough. The mandate to the N. C. S. is—Put your house in order. I am not in the war councils of the opposition, and therefore I do not know what the next stage in the campaign will be. But the writing is on the wall, plain for any man to see. The members of the N.C.S. do not mean to be blinded any longer by brilliant but ephemeral successes. They demand something more substantial. They want the finances of the society to be put on a sounder basis and they mean to have it. The present current of discontent will die down when the members see a prospect of a good reserve fund being built up, and not before. They do not question the energy which has been displayed in the management of the society's affairs. They do not dispute the claim of a vast increase of popular interest in the flower, but they want to see something solid as a result.

It is cheerful to be able to record a triumph over the transatlantic fruit shippers, considering how many they have been able to claim against us. All the autumn and winter the prices for apples have been abnormally high, yet American fruit was chiefly conspicuous by its absence. "Why do they not send?" was the question heard everywhere, and the wiseacre contemptuously responded, "Because they haven't got it." Now, however, nearly at the fag end of the season, there is quite a little rush of fruit across the streak. What have the agents on this side been about to keep it back so long? Did they argue that the tempting prices would go still higher when the best of the home fruit was gone? Probably that is the explanation, but it is a great mistake ever to let the markets get slack, because, after a disappointment or two, consumers give up asking for the article on the assumption that the season is over, and turn to preserved or tinned fruit. It is for this reason, I believe, that prices have broken, notwithstanding that there is no glut.

Mr. Radcliffe Cooke, M.P., has been writing to the *Field* about the fruit question in the West of England, and in this he makes a Lament, an Eulogium, and a Suggestion. The first is at the absence of skilled hands at pruning, grafting, and other cultural operations. The second is a doubtless well-deserved testimonial to the technical instructor in horticulture employed in Herefordshire. The third calls for an extension of the practical side of technical education. I do not myself wonder at the lack of skilled hands on the farms. So long as farmers think the wages of a common unskilled labourer suffice for providing all the requirements of fruit trees, so long will the skilled man confine himself to nurseries and private gardens, where better wages are paid. Those few farmers who are sensible enough to see that it is worth while to pay a little more than hedger's wages for a good pruner and grafter can usually get one.

Nevertheless, Mr. Radcliffe Cooke touches a weak point when he refers to the paucity of trained men on the farms. I have often noticed the same thing. If the Herefordshire instructor pursues his useful career things will perhaps improve, for Mr. Cooke speaks of his climbing into trees and showing good methods by demonstration. This is the right sort of man. Plenty of instructors are "up a tree" in another sense. They graft not, neither can they prune. But they can teach others. Strange, isn't it? When the GARDENERS' MAGAZINE gets the practical examinations for which it has long been fighting, it would not be a bad idea to specially invite all the technical instructors in the kingdom to offer themselves for a test. I mentioned this idea of mine to Peter, who, eyeing me with great favour, remarked with desperate meaning, "Yes, sir, and just you a-argue for me to be one o' the judges. I'd test 'em!"

LUX.

ROYAL HORTICULTURAL SOCIETY, MARCH 8.

"A BONNIE show, a bonnie show," was the expression used by one of the visitors to describe the exhibition held at the Drill Hall on the above date. It was indeed a splendid display for thus early in the year, and for such a bitterly cold day as was March 8. There were large groups of cyclamen, forced cherries, Azalea mollis, spiræas, deutzias, camellias, early spring flowers, clivias, amaryllis, ferns, and orchids, with a few vegetables and well-preserved fruits. There was also a large company to see the numerous exhibits, so much so that note-taking and locomotion were not easy, especially from two to four o'clock. We congratulate the society upon such a successful exhibition, and its superintendent, Mr. S. T. Wright, for the arrangement of the same.

FLORAL COMMITTEE.

Although there were few real novelties brought up for the consideration of this body, there were a very large number of groups, varied in size and contents, for the committee to adjudicate upon. The distribution of medals was less liberal than usual; but this does not, however, signify that the exhibits were less meritorious, but that there is a growing desire to set the R.H.S. awards at a higher value than of late.

Some comparatively new exhibitors set up a group of ferns; these were Messrs. J. Hill and Son, Edmonton. There were a number of fine large specimens of various maidenhair ferns, aspleniums, pteris, platyceriums, &c. In the foreground were baskets of small plants, all neat specimens of the more popular kinds of aspleniums, pteris, &c., and over the whole a large Dicksonia was suspended. A lovely display of Prunus pseudo-cerasus (P. Watereri) came from Messrs. J. Veitch and Sons, Chelsea, the beautiful pinky double flowers depending in fine clusters from the sturdy branching growths, and set off by young and delicate foliage. A batch like this would produce a grand effect in a conservatory or corridor. Staphylea colchica and Spiræa confusa were also staged in quantity by the Chelsea firm. A brilliant and imposing display of Azalea mollis varieties was arranged by Messrs. R. and G. Cuthbert, Southgate; all shades from palest buff to deep reddish-orange were on view, and in addition to these there were a number of Ghent azaleas in various colours. The bushes in every case were superb examples, and crowded with large substantial blooms. The St. George's Nursery Company, Hanwell, once again demonstrated their ability to produce good strains of cyclamen and to grow good plants; the collection staged included crimson, purple, rose, white and purple, and pure white varieties of great excellence, dwarf in habit and in a first-rate decorative condition. The Church Road Nursery Company, Hanwell, also showed a large collection of cyclamen in a great variety of colours, every plant being a perfect mass of bloom fringed by neat, clean and marbled foliage.

The yellow Richardia R. Elliottiana was a feature in the large and showy group of flowering and foliage plants staged by Messrs. W. Cutbush and Son, Highgate, N.; these were surrounded by neat-flowering specimens of Acacia cordata, A. Drummondi, Otaheite oranges, eriostemons, epacris, heaths, azaleas, &c.; Epacris Mont Blanc, a pure white-flowered variety, was a great feature in this group, and deserves to be better known and more widely cultivated. A charming set of the fragrant and elegant Boronia megastigma was sent by Messrs. Balchin and Sons, Hassocks Nurseries, Sussex; every plant was a perfect specimen, and crowded with its purple and orange flowers. A dozen and a half examples of Tetratheca pilosa, clothed with bright rosy flowers, also came from Hassocks, where all such subjects are remarkably well grown. Amaryllis from Messrs. J. Veitch and Sons, Chelsea, constituted a very bright display; the flowers were of fine shape and good size, and remarkable for their handsome colouring. In the group was a flowering specimen of the curious and rare Hippeastrum pardinum, but in point of effect the species does not compare favourably with the florists' form. Messrs. J. Laing and Sons contributed a collection of flowering and foliage plants; clivias were especially bright, and remarkable for their huge trusses. Richardia Elliottiana, amaryllis, streptocarpus, odontoglossums, and cœlogynes made up the bulk of the exhibit, and were associated with caladiums, crotons, dieffenbachias, palms, &c. A clivia with yellow striped foliage attracted no small amount of attention.

An exceedingly pretty group came from Mr. H. B. May, Edmonton, and consisted of small clematis arranged over ferns; five varieties were staged, viz., Lady Londesborough, Fair Rosamond, Sir Garnet Wolseley, Miss Bateman, and Mrs. Quilter; these were disposed in six groups each of about eight plants, and each plant carrying from four to a dozen fair-sized flowers. For conservatory decoration at this season such clematis would prove most acceptable, and Mr. May has done well to draw attention to them. Mr. Mount, Canterbury, again brought up some lovely roses; Catherine Mermet was represented by about three dozen blooms, and other good varieties were Mr. J. Laing, Captain Hayward, Niphetos, Mrs. W. Grant, The Bride, and Anna Olivier. Some of the flowers Mr. Mount staged with very long stems as cut, showing conclusively how high a standard of cultivation he has attained to. Cyclamen in good condition came from Mr. C. Turner, Slough, and maintained the reputation this nurseryman has long enjoyed for these useful winter flowers. Mr. P. Purnell, Woodlands, Streatham, made a pretty exhibit of daffodils in great variety, and also a number of early-flowering primulas, saxifragas, hardy cyclamen, irises, polyanthuses, &c.

A small collection of interesting spring flowers was staged by Messrs. Barr and Son, Covent Garden and Thames Ditton. Narcissus cyclamineus, N. J. S. Baker, N. minimus, Chionodoxa Luciliæ, C. gigantea, C. sardensis, Bulbocodium vernum, Anemone fulgens, several hellebores, crocuses, and forms of Erica carnea made up a pretty set of charming plants and flowers. Mr. John May, Gordon Nurseries, St. Margaret's, Twickenham, showed a remarkably fine lot of cyclamen; every flower was of full size, and set well above the foliage; with regard to number of flowers per plant, these were not so free as others in the hall, but they were far ahead in the quality of the individual blooms. Daffodils were well represented by Mr. T. S. Ware, Tottenham; N. Princess, Golden Spur, N. nanus, Henry Irving, and N. bicolor Victoria were the leading varieties, and shown in first-rate condition. Megaseas, Adonis amurensis, Scilla bifolia alba, Anemone pulsatilla, Primula denticulata alba, Tulipa violacea, Erythronium dens-canis, and some grape hyacinths made up an interesting frontage to the daffodils. A splendid group of camellias from Messrs. W. Paul and Son, Waltham Cross, came in for a share of admiration; the specimens were of fair size, clean in foliage, and carrying many handsome blooms; Double White; Monteroni, Ninfa Egeria, Beauty of Waltham, Mathotiana, Camilla Aureliana, Single Red, and Marchioness of Exeter were the varieties that seemed most attractive and imposing. Messrs. J. Peed and Son, Norwood, S.E., were represented by a big blaze of clivias and Azalea mollis, both grown in fine condition, and arranged with acacias, primulas, daffodils, lilac, and a few foliage plants; a most effective exhibit.

Some charming irises were shown by Messrs. R. Wallace and Co., Colchester; these were I. sindjarensis, I. orchioides, I. reticulata, I. persica, and I. alata, all beautiful little plants, and making up a very pretty little exhibit. Mr. T. P. de Langhe, Brussels, showed quite a large batch of his butterfly cyclamen; forms with spreading and fringed segments, and which have previously been described and figured in our columns. Mr. Newhall, Gateshead-on-Tyne, sent a truss of the fine Rhododendron argenteum. Messrs. J. Laing and Sons and Messrs. R. and G. Cuthbert staged azaleas. Mr. G. Cragg, gardener to W. Walker, Esq., Percy Lodge, Winchmore Hill, gained a cultural commendation for a grand specimen of amaryllis, carrying eleven brilliant crimson-scarlet flowers. The pretty Deutzea Crippsi was shown by Messrs. T. Cripps and Sons, Tunbridge Wells, in splendid condition, smothered in small clusters of pure white flowers. Some superb hippeastrums or amaryllis were staged by Mr. A. Chapman, gardener to Captain Holford, Westonbirt, Tetbury; these were so fine in form, colour, and substance that they attracted general attention.

ORCHID COMMITTEE.

Although not a very large display, the orchids were of more than usual interest, for there were numerous good, new, or rare subjects on view. This committee was in a liberal mood as regards awards and certificates, but to balance matters it was very chary of awarding medals to groups.

A handsome group of orchids came from Messrs. J. Veitch and Sons, Chelsea, and consisted chiefly of Dendrobium Wardianum, D. Euryalis, D. splendidissimum, D. Cybele, D. crassinode, D. Edithæ, and D. Wiganæ; the brilliant Sophronitis Veitchi came up again with a nice batch of Epidendrum elegantulum. Cymbidium eburneo-Lowianum with two spikes, was also very conspicuous. Under a bell glass a beautiful orchid was placed; this was a specimen of Phalænopsis John Seden, carrying two flowers; this is a cross between P. Luddemannianum and P. amabilis; numerous odontoglossums, masdevallias, cypripediums, &c., flanked the central bank of dendrobiums. Messrs Charlesworth and Co., Heaton, Bradford, put up a good exhibit, in which were some grand examples of Phaius Norman in three varieties, a beautiful hybrid between P. Sanderianus and P. tuberculosus, described elsewhere; odontoglossums were well represented, especially O. cirrhosum, O. Wilckeanum, O. crispum, &c.; this was a fine and interesting group to bring all the way from Bradford.

Messrs. Hugh Low and Co., Clapton, brought Dendrobium Brymerianum, Cymbidium Devonianum, O. crispum (a rosy form), O. nebulosum splendens, Cymbidium eburneo-Lowianum, and several handsome forms of Cattleya Trianæ. A famous lot of dendrobes, all examples of D. splendidissimum grandiflorum, came from Mr. Bond, gardener to C. L. N. Ingram, Esq., Godalming. The plants were all well grown, and the varieties and blooms all of the best; a cultural commendation was given. A pretty form of Cattleya Trianæ, with very delicate sepals and petals, was shown by Mr. Walters, gardener to Colonel Shipbury, Grove Park, Chiswick. Mr. Harris, gardener to P. Crowley, Esq., Croydon, showed a fine plant of the good old Cypripedium villosum, with about two dozen flowers. Cypripedium Mrs. H. Druce, shown by H. Druce, Esq., St. John's Wood, is a hybrid between C. niveus and C. bellatulum; this name is wrong for the hybrid is nothing else but C. Godefroyæ. Acineta Humboldti came from W. C. Walker, Esq., Percy Lodge, Winchmore Hill. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, sent the curious Pleurothallis punctulata. Messrs. J. Veitch and Sons sent Cattleya Miranda, a C. guttata cross, and Dendrobium Hildebrandi albescens.

Dendrobium Ainsworthi Woodhatch variety is a lovely form, shown grandly by Mr. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate; Lælio-cattleya Hippolyta, Haywood's variety, was also shown and greatly admired. Odontoglossum Wilckeanum Pittæ, shown by H. T. Pitt, Esq., Stamford Hill, proved a great attraction, the spike carrying eighteen handsome yellow flowers blotched with reddish chocolate; it is certainly one of the very finest of the Wilckeanum varieties. N. C. Cookson, Esq., Wylam-on-Tyne, sent Dendrobium Cybele and D. Astræ. A very beautiful plant of Dendrobium Wardianum album was shown by Messrs. Fisher, Son, and Sibray, Handsworth, Sheffield. Mr. J. Rutherford, Blackburn, staged a flowering specimen of the interesting Spiranthes colorans maculata. The lovely and brilliant Lælio-cattleya Warnhamiensis was brought by Mr. Duncan, gardener to C. J. Lucas, Esq., Warnham Court, Horsham. Mr. W. S. Barrill, gardener to W. S. Ellis, Esq., Dorking, showed Dendrobium Euterpe, D. Clio, and D. Cybele Ellis's variety, all beautiful orchids. A spike of the rare Epidendrum Stamfordianum was shown by Mr. Downes, gardener to J. T. Bennett-Poë, Esq., Cheshunt. Mr. Ballantyne, gardener to Baron Schröder, The Dell, Egham, sent three splendid spikes of the lovely Calanthe Baron Schröder, one very light and two dark coloured forms. Also from The Dell collection came a small plant of Odontoglossum crispum Baroness Schröder, a superb variety with rosy flowers almost covered with brilliant crimson blotches; other beautiful subjects were spikes of the pure yellow odontoglossum, O. coronarium, O. Pescatorei melanocentrum, O. microspilum, &c. It is a great pity that some better arrangements cannot be made by the Orchid Committee for displaying these grand orchids from The Dell; on this occasion the spikes were sheafed together in earthen bottles and pushed behind other orchids.

FRUIT AND VEGETABLE COMMITTEE.

Mr. R. Bullock, gardener to C. P. Serocold, Esq., Taplow Hill, was awarded a bronze Banksian medal for a small collection of apples, all in first-rate condition; Cox's Orange Pippin and Egremont Russett were splendidly kept. Mr. O. Thomas, gardener to H.M. the Queen, Windsor, sent his new cucumber named Every Day; this is a fair-sized form, with bright green skin and scarcely any tail; it gained an award of merit on February 8 last, and on this occasion gained a first-class certificate. Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, showed some fine bundles of asparagus produced in the open by the use of a covering of leaves; Mr. Wythes also sent some new and interesting artichokes, viz., Suttons' White, Vilmorin's White, and Syon Long White, the two latter being elongated forms. Messrs. H. Lane and Son, Berkhampstead, sent a basket of the famous Lane's Prince Albert apple, every fruit appearing to be as fresh as when gathered. An interesting exhibit of variegated and garnishing kale came from Messrs. J. Veitch and Sons, Chelsea. Mr. Empson, gardener to Mr. Wingfield, Ampthill, Beds, secured a silver Banksian medal for a collection of apples and pears, the majority being well kept. Mr. Bullock, gardener to C. P. Serocold, Esq., Taplow Hill, gained first prize for apples—flavour class—with Cox's Orange Pippin; Mr. Salter second, with Bess Pool. No first prize was awarded for pears, but a second was awarded to Mr. R. Maker, Yattenden Court, Newbury, for Bergamot Esperen.

MEDALS AWARDED.

Silver Gilt Flora Medals to Messrs. J. Hill and Co., for ferns; and to Messrs. W. Paul and Son, for camellias. *Silver Banksian Medals* to Messrs. J. Veitch and Sons, for orchids; ditto, for Prunus pseudo-cerasus; Mr. Mount, for roses; Mr. J. May, for cyclamen; Mr. Purnell, for daffodils, &c.; Mr. H. B. May, for clematis; and to Messrs. R. and G. Cuthbert, for Ghent and mollis azaleas. *Bronze Flora Medals* to the Church Road Nursery Company, Hanwell, for cyclamen; and to the St. George's Nursery Company, Hanwell, for cyclamen; and *Bronze Banksian Medals* to Messrs. Charlesworth and Co., for orchids; and Messrs. J. Laing and Sons, for clivias, &c.

WATER IN THE GARDEN.

Large Streams, Ponds, and Lakes.

HAVING already described the various forms of water on a comparatively small scale, and chiefly in connection with rocks, I will now deal with water of greater extent and generally without rocks. Stagnant ponds of large size are even more repulsive than small ones, but ponds fed by a streamlet or brook ensuring a constant supply of fresh water are most desirable in the park or pleasure-grounds, and the water itself, as well as its banks, should be full of life and beauty, and display that picturesque charm which is the true character of a water garden. It goes without saying that the shore-line of such a pond, in order to be picturesque, must be as varied as possible, and the water itself should contain plants naturally grouped without being entirely covered with them. The reflecting surface of water gives light to the landscape, and a sheet of water entirely covered is monotonous. I recently saw a pond nearly an acre in extent in which the water is entirely obscured by the Cape pond weed (*Aponogeton distachyon*). Beautiful as this plant may be with its delightfully fragrant flowers, when kept within proper limits, the effect is simply dismal when the plant is allowed to spread over the whole of the surface to the exclusion of every other plant. Variety is charming, and when we have an enormous number of suitable plants of all shapes and sizes to choose from, there is really no excuse for monotony.

A beautiful example of a picturesque pond is the one at Enys, Cornwall, a portion of which is here illustrated. Enys, the property and residence of Mr. F. G. Enys, is one of those delightful sheltered spots within a few miles from Falmouth, where sub-tropical plants, but seldom met with out of doors, grow luxuriantly; but one of the greatest attractions of this place, where Mr. P. Hogbin has charge, is its pond. The engraving shows, of course, only a very small portion of this pond, but this water garden is even more irregular and more picturesque than can be conveyed by the illustration. The size of the figure in the boat will give an idea of the dimensions of the fine specimen of Gunnera manicata in the background; this ranks among the finest in Cornwall, having leafstems seven feet long and leaves over nine feet in width. Handsome ferns, hydrangeas, rhododendrons, and fine conifers supply an excellent background on the other side of the pond. In the pond itself are masses of the bold American Nuphar advenna, Nymphæa alba, and several of the newer kinds of Marliac's lovely hybrid water lilies. A sight altogether unique is met with on the shore opposite to that seen in the picture. Here, beneath the shade of lime trees, thousands of Primula japonica, in luxuriant growth, rear their whorls of brilliant crimson-purple flowers, forming (close by the waterside) an imposing bank some one hundred and fifty yards in length. Quite recently specimens of the bright yellow Primula sikkimensis have been added to this bank, and promise to be a great success. There are many other water gardens in Cornwall, and perhaps the most extensive is one at Carhayes Castle, near St. Austell, which, although of comparatively recent construction, is furnished with all the latest introductions in the way of aquatics, and will in a few years' time be most picturesque. Probably the finest water garden in Great Britain is the one owned by Mr. W Robinson, at Gravetye Manor, Sussex. Here Marliac's magnificent water lilies in all shades of colour were planted and flourished to perfection almost before they were in commerce. Before they were so generally known as they are now, I saw the pond at Gravetye literally aglow with masses of these brilliant waterlilies, some of them already covering a space many yards in diameter.

Construction of Ponds and Lakes.

Too often, unfortunately, we may still see ponds of circular or oval shape with banks secured by stone walls or pebbles set in cement concrete that show above the waterline. This may do for the horsepond of a farmyard but it will not do for a water garden. If it is worth our while to make a pond at all it should be also worth our while to pay attention to Nature's most simple laws with regard to beauty, and when an artificial pond shows in its shore line curves that could not possibly have been formed by Nature the effect is repulsive. When writing of water in the rock garden I mentioned that a pond in most cases should be treated as an expanded streamlet, and the curves of large ponds or lakes give no exception to that rule. A natural pond with a bold projection or promontory on one side will almost invariably show a still bolder recess on the opposite shore, and *vice versa*. If such projections are covered by vegetation that hides a portion of the water, so that from no point the whole of the surface can be seen, the effect will be all the more picturesque. A good example of this may be seen in the lakes at Birkenhead Park, which, in consequence of this partial obscuring of the water from certain points, appears much larger than it really is.

In the case of a broad stream or river flowing through some meadows within sight of the house, the simplest way to produce a pond or lake would, of course, be to widen the stream or river to the size that would seem most desirable. But, if the pond and its banks are intended for a water garden this course would not be the most practical if the flow of water is at all rapid, because, after heavy rains, when the river swells and floods its surroundings, there would not only be a danger of the water plants being carried away, but silt, gravel and river mud would quickly fill up all recesses and thus practically destroy the beauty of the pond and choke the plants. The best plan in such a case is to "tap" the river, conduct the water intended for the supply of the pond some distance away from the original stream, and finally let the overflow rejoin the river at a lower level If the water is first conveyed in pipes and made to flow in an opposite direction to that of the river, the danger of chokage by mud or silt will be entirely avoided. When laying out some grounds at Great Marlow a few years ago, I made a most successful pond in the way just described, by tapping the river Thames. In most cases it may also be advisable to cover the mouth of the pipe by wire netting to keep out water rats and other vermin. There is no reason why water drawn in this way from a river should not, at some little distance from the "tapping place," reappear in the shape of a natural streamlet before filling the pond, and here and there its water-soaked banks might become the home of all kinds of most suitable as well as beautiful plants. In a like manner the water emerging as overflow from the pond might form a picturesque brook of any desirable length with or without waterfalls before rejoining the river.

In a case like the preceding where the water supply would be practically unlimited, the comparatively small waste of water through absorption by the banks and perhaps also by the bottom of the pond would hardly need comment. But where the supply is scarce and the bottom and sides of the pond are of a porous nature the latter would have to be either "puddled" or covered with concrete to prevent waste. Concreting on a large scale is always expensive work, and clay puddle, especially on the sides or banks, is very apt to be injured by water rats, to crumble away after severe frost, or be washed away by the ripples of water moved by wind. Sometimes it so happens that the subsoil consists at a certain depth of a tough clay, which no water could pene-

VIEW IN THE WATER GARDEN AT ENYS, CORNWALL.

trate, but that the soil at the required water level is of so porous a nature that it would not hold water. Naturally, the first impulse in such a case would be to excavate the pond to the depth of the natural layer of clay, and then form banks of clay puddle at the sides. But there is a much cheaper and more simple plan. Instead of excavating to the clay, excavate only to a depth sufficient for growing aquatics (say two or three feet), and instead of piling up clay against the sides leave the sides untouched as much as possible, preferring the natural slope of the ground to dip below the waterline. To prevent waste percolation, surround the whole pond by a trench about eighteen inches wide excavated beyond the depth of the natural clay subsoil. The whole of this trench should then be filled with clay-puddle to a height extending slightly above the water level, filling up the remainder with ordinary soil, so that the whole is completely hidden. The trench should not be close to the shoreline, neither need it follow the curves of the shore, but, as it would be invisible when finished, it might even be perfectly straight in some places if this would be a saving in distance. The advantages of this system are obvious. The water-tight puddle would be situated where it would neither wash nor crumble away. But the greatest advantage is that the ground intervening between the trench and the actual outline of the pond would be continuously soaked, and a natural bog for plants that love the waterside is thus formed without much trouble.

Very frequently a pond most suitable for a water garden can be formed by throwing a dam across a valley traversed by some streamlet. Generally, this is effected by a straight or slightly curved wall, which is afterwards covered with soil, turf, and plants, with an opening from which the overflow water may emerge as a waterfall. As a rule such an opening is left near the middle of the dam and looks most unnatural, because the overflow emerges from what would be the broadest side of the pond. In Nature, this could scarcely ever occur. If we observe the natural formation of ponds, we find almost invariably that a streamlet becomes gradually wider and wider till a lake-like expanse is formed; it then almost just as gradually contracts, and finally emerges again as a narrow streamlet. If the dam has to be made it would, therefore, be much more natural to have two walls gradually contracting till the desired outlet or overflow is provided. Any formal edging of stones or any other material around a pond would at once deprive the latter of all natural appearance, however carefully it might have been constructed. The best way of securing the shoreline against crumbling and washing, is to round off all edges till they form a gentle slope, and then lay down long pieces of good tough turf, which should be continued quite a foot below the watermark, and should be further secured by long sticks driven firmly through them and into the bank.

Islands in ponds should be arranged with due regard to such formations in Nature. In natural lakes we find them not often in the middle, but generally just beyond a promontory, where they would justify the idea of having been severed from the mainland by the breaking through of the water, or if they are of a rocky nature, by upheavals from the bottom. A circular mound of soil in the middle of the pond generally looks as ugly as can be, and most unnatural.

Exeter. F. W. MEYER.

SPRING-PLANTING TOMATOS.

ALL tomato growers will be more or less busy making a start at planting. I, among others, would be glad if we could wait a week or two longer, even into April, as we should have far less trouble and much more satisfaction in the results. With vines to be started we plant out tomatos according—and though potato-baiting the whole ground before planting, sometimes we find it extremely difficult to master that busy underground pest the wireworm. Strong plants are put in, and then, even with all the heat necessary for the vine growth and with good sunshine, only a slow growth is made. The roots take hold of the soil, but top growth always seems backward at this season. Our space is against growing more than a thousand plants in a batch; and as fast as we plant out the pots are washed and again filled, the second batch always carrying far the heaviest weight of fruit. The ground cannot be too well worked before planting tomatos; in my own case digging where practicable is practised, followed by forking more than once to thoroughly pulverise the soil. This, though it may encourage the wireworm, gives us the opportunity of reducing the pest each time we are at work, and we know well that roots in such soil quickly start business. We plant out from forty-eight-sized pots so as to have a good start, and are always careful to only just cover the surface of the ball, as it is found that deep planting encourages the wireworm to enter just at the base of the stem. The tomatos, being well watered before planting, require but little for some time after, and so long as the soil is fairly moist the less water given the better for the plant, as watering lowers the temperature of the soil. We have also proved that roots at this time of the year take to the new soil quicker when the borders are not too wet. A quick root-start will, of course, mean better results above ground. Varieties of tomatos are numerous, and each grower has his own selection, but all ours for the later planting will be of the Chemin Rouge type, as after June fruits of the Old Red class are difficult to market profitably.

Bottesford Vineries, Notts. STEPHEN CASTLE, F.R.H.S.

Horticultural School.—M. Durand-Gasselin who, under the will of M. Dobrée, has inherited a fortune of nearly thirty million francs, has presented to the Department of Loire Inférieure the sum of three hundred thousand francs for establishing a horticultural school, and one million francs for the erection of plant houses for the cultivation of exotic and colonial plants for the improvement and decoration of parks, gardens, and buildings. The horticultural school will be formed in the park Grand Blattereau, a short distance from Nantes, in the commune of Doulon.

THE BEARDED DISAS.

USUALLY it is not surprising to find considerable diversity among species of a large genus. But I am afraid a first acquaintance with many of the hundred species of disas would produce incredulity, even in the botanist, as to their connection in one genus. The varied habit and as varied development of different parts of the flower have afforded means to divide them into ten well-defined groups, and that with few of their species so similar as to be easily mistaken for each other. Indeed, so marked are the characters of some that they were formerly known under the titles of their respective groups as distinct genera. As constituted at present, the group Endisa contains the species with most diverse habit and external appearance; and in the five species under Herschelia is found the greatest uniformity. These two and the Vexillata section furnish the largest and most beautiful flowers of the genus, with colours ranging from various shades of blue, through green and yellow, to vivid scarlet.

In the Herschelia group, to which I shall confine these notes, the lip is usually bearded, and the odd sepal developed into a perfect hood with a short blunt spur, while the side sepals spread out well between them and complete a distinct form of flower. The tubers of all are extremely large, and the foliage is long and narrow. Disa graminifolia and D. purpurascens are the exceptions as regards bearded lips; the others are D. barbata D. lugens, and D. venusta; these have flowers of a [illegible] blue with a white or purple lip, which is, however, very variable in tone and intensity. Dotted about in broad, open spaces the brightly coloured flowers of these disas are very pleasing, and at a distance appear as strings of quaintly-shaped butterflies fluttering above the waving grass. These three latter species are found in very porous soil, most nearly resembling a sandy peat, and are directly dependent on the rains for a supply of moisture. D. venusta and D. purpurascens flower towards the end of November, usually after the rains have ceased for the summer. This season heavy showers extended to the end of that month, but at lengthened intervals, and the abundance of flowers shows the season to have been more favourable for them than when an early drought sets in, as in last year. It is a well recognised fact here that disa blooms are much more plentiful some seasons than in others; and apparently it is the extension of the rains that governs the supply of those found in the open. That all, excepting D. graminifolia, have a decided rest is certain. But the glossy character of the restios, the dry grasses, and the sandy soil of the valleys or slopes in or on which they are found combine to counteract the parching effects of the sun during that period.

It is also certain that sufficient moisture to keep the tubers fresh and plump will rise by capillarity, as the underground supply is not so rapidly exhausted or lowered as in stiff soils, which crack deeply and allow the moisture to be licked up by the winds. That really it is only the surface which becomes very dry I had convincing proof when lifting a few corms of Antholyza lucida on a slope which received the pitiless rays of a February sun. About a foot down, among pieces of rock imbedded in a hard soil, they provided me with more laborious and exhausting work than I should have previously imagined could be put into half an hour. Putting my hand in the holes the hot moisture felt just as one feels it when entering a recently-closed plant stove. And this is what I want to enforce—that even those bulbous plants found in the driest positions are not subjected to so absolutely dry a rest as is generally imagined, for by the character of the vegetation or the nature of the ground the parching effect of the sun is minimised, and evaporation considerably restrained. That many bulbs are capable of withstanding severe and prolonged drought is undeniable, some even for years; but they are not then seen at their best, although having been subjected to such conditions may assist towards their better development in the season of heavy rains. As witness the "blaze of colour" one hears of in the arid regions after heavy rains. How readily they must respond to the more favourable conditions to produce such an effect in a few weeks one can but imagine. The same may be said of the bulbous plants in this district, but in a less degree; for the rains, varying much in quantity and prolongation in different years, are more constant in their seasons. However, I am digressing somewhat, but the subject is so interesting that one is apt to wander.

To return then: Disa barbata bears in October from two to four faintly-pencilled white flowers on slender scapes from fifteen to twenty inches in length. Occasionally flowers are seen with a lilac lip, adding much to their quaint appearance. A decided preference is evinced for a blackish sandy soil, where discoloured water is standing in furrows during the time of growth and flowering. It is partially sheltered from wind and sun, and flowering earlier than its congeners, neither has the sun so much power as when they are in bloom, nor will it become as dry when at rest, although it does occur as stragglers in drier places than the spot described. D. venusta, D. lugens, and the above are confined to the districts which are in no place many feet above sea-level. The valleys D. purpurascens favours are several hundred feet in elevation, and the slopes D. graminifolia beautifies are over a thousand feet above the sea. The conditions of D. graminifolia were described in the issue of May 8th, 1897, and, as there noted, it does not commence growth until the wet season is well advanced, or rather it apparently does not. For a considerable time I was unable to understand this peculiarity. So inquisitiveness led me to do a very un-gardener like action, *i.e.*, to lift some transplanted tubers to see what they were doing. They were collected in February, when in flower, and planted immediately. During May I first examined them and found no sign of roots or leaves; but at the shoulder of the tuber was a peculiar wart-like excrescence, which in July had sufficiently developed to indicate that it was a new tuber. At that time the old tuber was decidedly shrivelled, thus showing the source of nourishment. Unfortunately the inevitable effect of such treatment showed itself in the rotten tuber when next examined. So I am unable to decisively [illegible] the peculiarities of this lovely disa, but sufficient was seen to [illegible] the imperative need of moisture at a time when no visible activity is taking place, and this will supply a key to the inability to cultivate it if the usual method of withholding a free supply of water until signs of growth are apparent, is adopted. An excellent figure of this species in Bolus's "Orchids of the Cape Peninsula," shows only the neck of the tuber. But in that of D. ferruginea, which has the same peculiarity apparently, a shrivelled tuber is shown behind the plump one bearing the scape and leaves. My previous statement that the tubers were perennial is therefore erroneous. But the interest is none the less, for the one peculiarity is as equally unusual as the other.

To sum up then: After a warm, even hot, but moist rest an abundance of water must be given during leaf growth, gradually lessening the supply as the flowers develop, until, when they are over, only sufficient is given to keep the tubers plump. A maximum amount of light or sun with a buoyant atmosphere always are doubtless equally essential as an open porous soil. The greatest deterrents would seem to be a stuffy atmosphere, and stagnation at the roots, except perhaps with D. barbata, which is only a foot or two above standing water for a greater part of the year.

Cape Town. J. W. MATHEWS.

NOTES ON ROSES.

I WAS much interested in the article upon the parentage of roses (page 111). Like Mr. Williamson, I would be pleased to know the parentage of many of our most popular roses; but this is somewhat difficult to discover, for until quite recently few raisers took the trouble to carefully and systematically cross the varieties. I am rather surprised at two statements in the article. Ulrich Brunner is not of German origin, but was sent out by M. A. Levet in 1881. Doubtless the German name led to confusion. Then the remark that Charles Lefebvre lacks "quality and strength of perfume" is rather startling. To my fancy it is one of the very sweetest scented roses we have; and that this was the general opinion of the Catalogue Committee of the National Rose Society is fully proved, for they added the remark, "one of the best roses grown; very fragrant." We find a certain perfume in several of our dark hybrid perpetuals that rivals the best of the old damask roses; Alfred Dumesnil, Duc de Montpensier, General Jacqueminot, Mons. E. Y. Teas, Lord Macaulay, Harrison Weir, Earl of Dufferin, Maurice Bernardin, Pierre Notting, A. K. Williams, Captain Hayward, and Red Dragon are a dozen which occur to me as I write.

But to return to the parentage of roses. How varied and surprising are some of the offspring from crossing two varieties to what might at first have been expected. But when we look back to the grand and great grand parents we find such distinct cases of atavism that we can have no doubt careful hybridisation may result in some startling developments and changes yet. M. Guillot stated that Gloire Lyonnaise was the result of successive crossings of Madame Falcot and Baroness Rothschild. It is generally accepted that Mabel Morrison and Canari were the parents of Her Majesty; that Madame Falcot and Perle des Jardins were the parents of Hon. Edith Gifford—two yellows producing a white or creamy blush; at first sight these appear almost impossible departures, but if we look back there is little doubt the matter might be explained. In the present day we are, happily, giving more attention to fertilisation, instead of collecting seed in the haphazard manner of the past. A list of new roses for the present spring contains no less than thirty-eight that have their parentage attached. When a grower has mastered some of the secrets of successful hybridisation, he is naturally chary about letting the general public have the benefit of his knowledge and methods. Last summer, in one of my short contributions to the GARDENERS' MAGAZINE, I mentioned that Maman Cochet was a seedling from Catherine Mermet. A leading amateur wrote me asking if I had any authority for this, or whether it was assumed from the habit of growth, &c. Since then I have had a card from M. Scipion Cochet, stating definitely that the variety was obtained from seed gathered from Catherine Mermet; but there is no mention, nor, so far as I can discover, any knowledge of the other parent. We are now promised a white sport from Maman Cochet, under the name of White Maman Cochet, with all the good qualities of that grand variety, and if the description is correct it will be a great and welcome acquisition.

The time for pruning has come round again, and we need bear in mind the objects for which we are pruning. No hard-and-fast rule can be laid down; but if we prune our weak growers rather hard, and scarcely use the knife among those of extra vigour, except to boldly thin out overcrowded growths and old wood, there will not be much amiss. The wood has come through the winter months exceptionally sound and well ripened, so that unless late frosts cripple young growths, we should have a grand display upon our walls and among the more tender of our vigorous-growing garden roses. My own roses will not be pruned until the second week in March, experience having proved that a later break from the lower eyes will generally grow on so fast and free from checks as to catch up much of that growth which was well advanced while they were almost dormant. Excellent articles upon pruning have appeared in these pages from time to time, and some of them illustrated in such a plain manner that there should be no need to go fully into this subject again.

Our roses under glass seldom looked better than at present, and are now well in flower. The main points are to keep such free from insect pests, the temperature fairly regular without much ventilation, and to help all established plants with liberal doses of weak liquid manure.

A. PIPER.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book, containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. Price 1s. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

NATURAL FERTILITY OF SOILS.

THE gardener's and farmer's aim is to bring the soil under cultivation up to its maximum of productiveness. This state of fertility is not attained by heavy manuring and digging, but rather by a knowledge of the composition of the soil, the requirements of the plants to be grown upon it, and the influence certain manures will have upon both. With such soils as resemble that formed from the red sandstone rocks met with in the vicinity of Kelsall, in Cheshire, the cultivation of garden and farm crops is made easy, as it is naturally rich in the necessary constituents of plant food. Of course the constant drain of phosphates and nitrogen from the soil by crops necessitates frequent applications of manures containing these ingredients, but not so much phosphorus and nitrogen will be required to maintain the balance of healthy growths on such a medium, as on some of a less naturally fertile character. Besides being a loam of the best quality chemically, it is also physically one adapted to the utilisation of the cheaper forms of manures, and easily tilled. Instead of bone meal, superphosphate, fish guano, and other forms of costly phosphatic manures, basic slag serves the purpose of supplying phosphorus and lime to meet the needs of growing crops. Sulphate of ammonia, mixed with one quarter of its weight of nitrate of soda, or rape dust, put on and ploughed or dug in in early autumn, will keep up a supply of the indispensable nitrogen. Both cereals, grasses, and roots are abundantly yielded by all the land for miles around Kelsall, and gardening is made a simple process.

Among ornamental trees and shrubs, the holly, hemlock, spruce, and in fact, all conifers, grow luxuriantly. The laurustinus, which is usually met with in a dwarf twiggy state, develops here into a robust shrub of something like six feet in height, with a mass of strong shoots, large healthy leaves, and heads of flowers three inches across. The conspicuous feature, however, looked at from a horticultural point of view, is the suitability of the soil for fruit culture. Apples, pears, and plums, do exceptionally well, and damsons grow like weeds. Vines, too, are quite at home, and without any coaxing, grow vigorously, and yield heavily. With such a soil examples of produce will be obtained, which lead the cultivator to entertain the belief, that by his skill (?) prodigious results have been brought about. When we look at a soil like the one referred to, and one of an inert nature, and compare the amount of brain and physical exertion required to secure satisfactory crops from both, it is an easy matter to grasp the situation and see how some are handicapped in the production of garden produce. A soil not only serves the purpose of holding plants in their natural position, and supplying the larger portion of the food they require, but it also serves as the kitchen in which the food, abstracted by the plants from the soil, is cooked. The value of a soil for the cultivation of any useful crop depends as much upon its power to manufacture food materials for the supplying of plants, as upon its own power to yield them. Basic slag would be lost on sandy soils, unless they contained a high percentage of organic matter, and a heavy one usually contains too much iron, and is impervious to air, and consequently warmth, that manures lie a considerable time in it before becoming active. For this kind of land lime is, perhaps, the best thing to apply, but without some idea as to the part it plays in the soil harm, as well as good, may be done.

There is an old saying, and a true one, which every gardener and farmer should know, viz., "Lime enriches the father and beggars the son." Lime dissolves the organic parts of soils, and renders their constituents available to plants. If too much lime be applied, the rains will carry away into the drains the food that ought to have remained in the soil for succeeding crops, and the soil will become so poor in vegetable matter that only inferior crops can be secured from it. Lime is an indispensable constituent of all fertile soils, as it is one of the ingredients necessary to plant growth. Knowing this, we also know that lime must be incorporated with the soil periodically, except when dealing with calcareous formations. As most of the phosphatic manures—in truth, all of them—contain from a half to three fourths of their bulk of lime, every time any of them are supplied to the soil we know that a certain amount of lime has been supplied at the same time. By an indiscriminate use of lime on the red sandstone loam of Kelsall its natural fertility would be crippled for years; whereas the heavy clays would suffer less, although they, too, in a few years after the dressings would manifest declining productiveness.

CESTRIAN.

Prize Awards and Point Value.—The granting of prizes at flower shows on the purely point value basis is not at all common practice. The chief application of the method so far has been found at Carshalton, on the August Bank Holiday, when a sum given by Mr. Smee of £5 is regularly apportioned in several prizes for collections of nine dishes of vegetables. The issue of the schedule for the Shrewsbury Show in August next, however, recalls the fact that Carshalton has found a very important and influential imitator. At the Great Shrewsbury Show two large classes will be judged entirely on their point value, and five prizes will be in each case awarded of equal money value to the point value. The first is the Great Decorative Fruit Table Class, for which is set apart the large sum of £45. Ordinarily this would be divided into prizes arbitrarily fixed, as last year, when, only four prizes being offered, they were £17 12s., £12 12s., £8 8s., and £5 5s. Here was evident great disparity, whilst the point values of the collection showed comparatively trifling difference. This year rather more money is added, and one additional prize. It will, therefore, be no matter of surprise should the awards show cash prizes of trifling diversity also. Then in the Garden Produce Class—left out of the schedule last year to make room for a Victorian Class—to which a sum of £25 is allotted, the same principle of point value will be applied. The average of the sum is £5, but it is probable that the awards may, if the competition be keen, range from £5 10s. to £4 10s. So that if the first-prize winner gets less than before, the other prize winners at least get more in accordance with the merits of their exhibits. Now that Shrewsbury has shown a lead in this just method of apportioning prizes, it is hoped that other societies will follow suit, and eventually make the principle universal.—A. D.

PATRIARCHIAL GARDENERS.

The occupation of gardening is reputedly one of exceeding healthiness, and as a result, it is naturally looked for that those who work at it should live to great old age. It does not seem as if facts bear out this supposition, whilst most of us who are actively engaged in horticulture know that very old practitioners are not numerous. Very striking in reference to this matter was the list of candidates, all gardeners, who recently applied to be elected as pensioners on the Gardeners' Benevolent Institution, and, exclusive of widows, there were thirty-four of such applicants, and of these there were twenty in the seventies, and no less than fourteen in the sixties. The oldest was seventy-nine, and four others were seventy-eight years old—oddly enough not one of these aged persons was elected. The youngest was sixty years of age only, and some others were but a year or two older. It does not say much for the assumed healthiness of the gardening profession that so many persons should, at so comparatively an early age, thus be forced to appeal for charitable help.

Mr. W. Smythe.

Reading over this list with appended ages, so sad in its associations, my thoughts reverted to a brighter aspect in remembering some very aged men, yet playing their parts in gardening, and doing it well too, with wonderful vigour and energy. I know some well in the seventies putting to shame many others not one half their age who greatly lack force and vigour. There is one whose portrait is so admirably presented here, a gardener who has been hard at work for more than sixty years, and is to-day astonishingly vigorous and active. This is Mr. W. Smythe, still gardener at Basing Park, Hants, the seat of W. Nicholson, Esq. This septuagenarian tells that he began work at twelve years of age in the garden of Captain Booth, Ufford Place, near Woodbridge, Suffolk, where he remained five years. The natural conclusion, therefore, is that he was an industrious lad and did well. Next, whilst very young, he undertakes charge of a garden at St. John's Wood for four years; then he was three years with Hendersons, of Pineapple Nursery, in that day almost the leading plant nursery of London; and from there he was sent as foreman to that once famous garden, Cooper's Hill, Egham, then in the occupation of Mr. John Cathcart, who was a liberal horticultural patron. His next situation was that of gardener to the once famous racing baronet, Sir Joseph Hawley, being recommended for the position by Mr. Thomas, then a well-known landscape gardener. Here he set out the new gardens, erected conservatory, and various plant houses and vineries, and in doing much good work gained experience also. Later he entered the service of the Rev. John Matthew, in Dorsetshire, and here again laid out the grounds, erected houses, and thoroughly made the place. Through death, however, his engagement here terminated in eighteen months; and from there he came to Chelsea, and was for a short time with the firm of Messrs. J. Veitch and Sons, who later sent him to Almham Hall, in Norfolk, the seat of Lord Sondes, where he remained nineteen years, leaving there again after a death in the family. Finally he engaged as gardener with his present employer, Mr. Nicholson, with whom he has lived honoured and esteemed, some twenty-two and a half years. His is a very varied and long term of work, one of which any man may well be proud. It is the working life of a man who is now seventy-five years of age, and looks as hearty and is so active, that he may even yet put in many years more of labour at Basing Park.

Mr. Smythe has always been interested in crossing and hybridising, and has produced many excellent things, and his latest efforts in that direction seem to have been with kidney beans, for the strain known as "Smythe's Hybrids" are of his production. He crossed dwarfs and scarlet runners originally with much success; then he again crossed the scarlet runner with Canadian Wonder, and also with one of his best dwarf hybrids. From these crosses came the two very fine dwarf beans shown to the Fruit Committee at the Drill Hall on August 10 last year. The product of the latter cross, named Goliath, was undoubtedly one of the finest and most prolific dwarf beans ever seen; and if it keeps true when put into commerce, as it probably will be next year, it will doubtless be very popular. One of the most important of the ornamental plants raised by Mr. Smythe is Tacsonia Smythiana, obtained from a cross effected between T. mollissima and another species. Basing Park, Mr. Smythe's present location, is a beautiful place, famous in history as the site of Basing House of Cromwell's time; and lies almost midway between Alton and Petersfield. When the new light railway being constructed to run from Basingstoke, viâ Alton, down the valley to Fareham is completed, Basing Park will be very accessible.

A. Dean.

Pickled Gherkins.—These are small young cucumbers, used almost exclusively for pickling. The best ones for the purpose are those about three inches and a half long and one inch in diameter, when less than this they have very little flavour. Rub off the rough, prickly skin with a clean cloth and some dry salt, then throw them into boiling vinegar, simmer for five minutes. then drain, and place in suitable jars and bottles. Distribute the various spices as evenly as possible, pour the vinegar over, and when cold finish off in the usual manner. Allow for every quart of vinegar half an ounce each of salt and whole pepper, a few sprigs of tarragon, a large blade of mace, and half a dozen cloves. —Housewife.

CYPRIREDIUM SANDERO-SUPERBIENS.

Direct or first hybrids of cypripediums are almost always of great interest, as combining the salient features of both parents, or they are of considerable beauty and usefulness. Very few of the first hybrids are failures. When two such distinct species as C. Sanderianum and C. superbiens are used as parents it is easy to foretell that the progeny will also be distinct. C. Sanderianum was discovered by Forstermann when collecting in the Malay Archipelago for Messrs. F. Sander and Co., St. Albans, and sent home about 1885. According to the newer nomenclature this should be a paphiopedium, and it is of more than passing interest inasmuch as it almost provides the missing link between what we have hitherto known as cypripediums and selenipediums. C. superbiens is now a well-known orchid, though not over abundant in collections; it was introduced in the first instance by the Messrs. Rollison in 1855, and two years later by the Messrs. Veitch, each [illegible] obtaining one plant only, and from these the present cultivated stock has been propagated. The nearest ally of C. superbiens is C. Curtisi, the latter being more robust and with bolder flowers.

C. Sandero-superbiens is due to the efforts of two successful orchidists and hybridisers, Captain Vipan and Mr. N. Cookson. The former crossed the two species and carefully watched over the seed-parent until the seed was ripe. Part of the seed was given to Mr. N. Cookson, Oakwood, Wylam-on-Tyne, who was the first to bring a seedling to the flowering stage On August 29, 1893, this specimen was exhibited at a meeting of the Royal Horticultural Society, when an award of merit was granted. The accompanying illustration represents a specimen staged by Mr. Cookson at the Drill Hall, Westminster, on February 8 last, and one that was greatly admired for its robust habit and fine bold flowers. The foliage reminds one forcibly of Cypripedium Curtisi both in size and mottling. The flowers are borne two together on a tall blackish scape. The dorsal sepal is greenish white, striped and lined with very dark purplish brown; the apex of this organ is very acutely pointed. The petals, long and depending, show in a marked degree the influence of C. Sanderianum; the ground colour is a peculiar shade of greenish yellow, and on this are numerous and somewhat heavy, irregular dots of purplish brown. The labellum is very prominent, large, and pouched, as in C. superbiens or C. Curtisi, and of a dark brown colour, though slightly paler at the mouth; the infolded side lobes are dotted with purple brown. Altogether C. Sandero-superbiens is one of our stateliest cypripedes, and in a general way can only be compared with the lovely C. Morganiæ. Messrs. J. Veitch and Sons were true prophets when they described the then new C. Sanderianum as being one of the handsomest of cypripedes, and supplying the hybridist with a most distinct agency for the production of new and interesting forms.

SPRING CABBAGE.

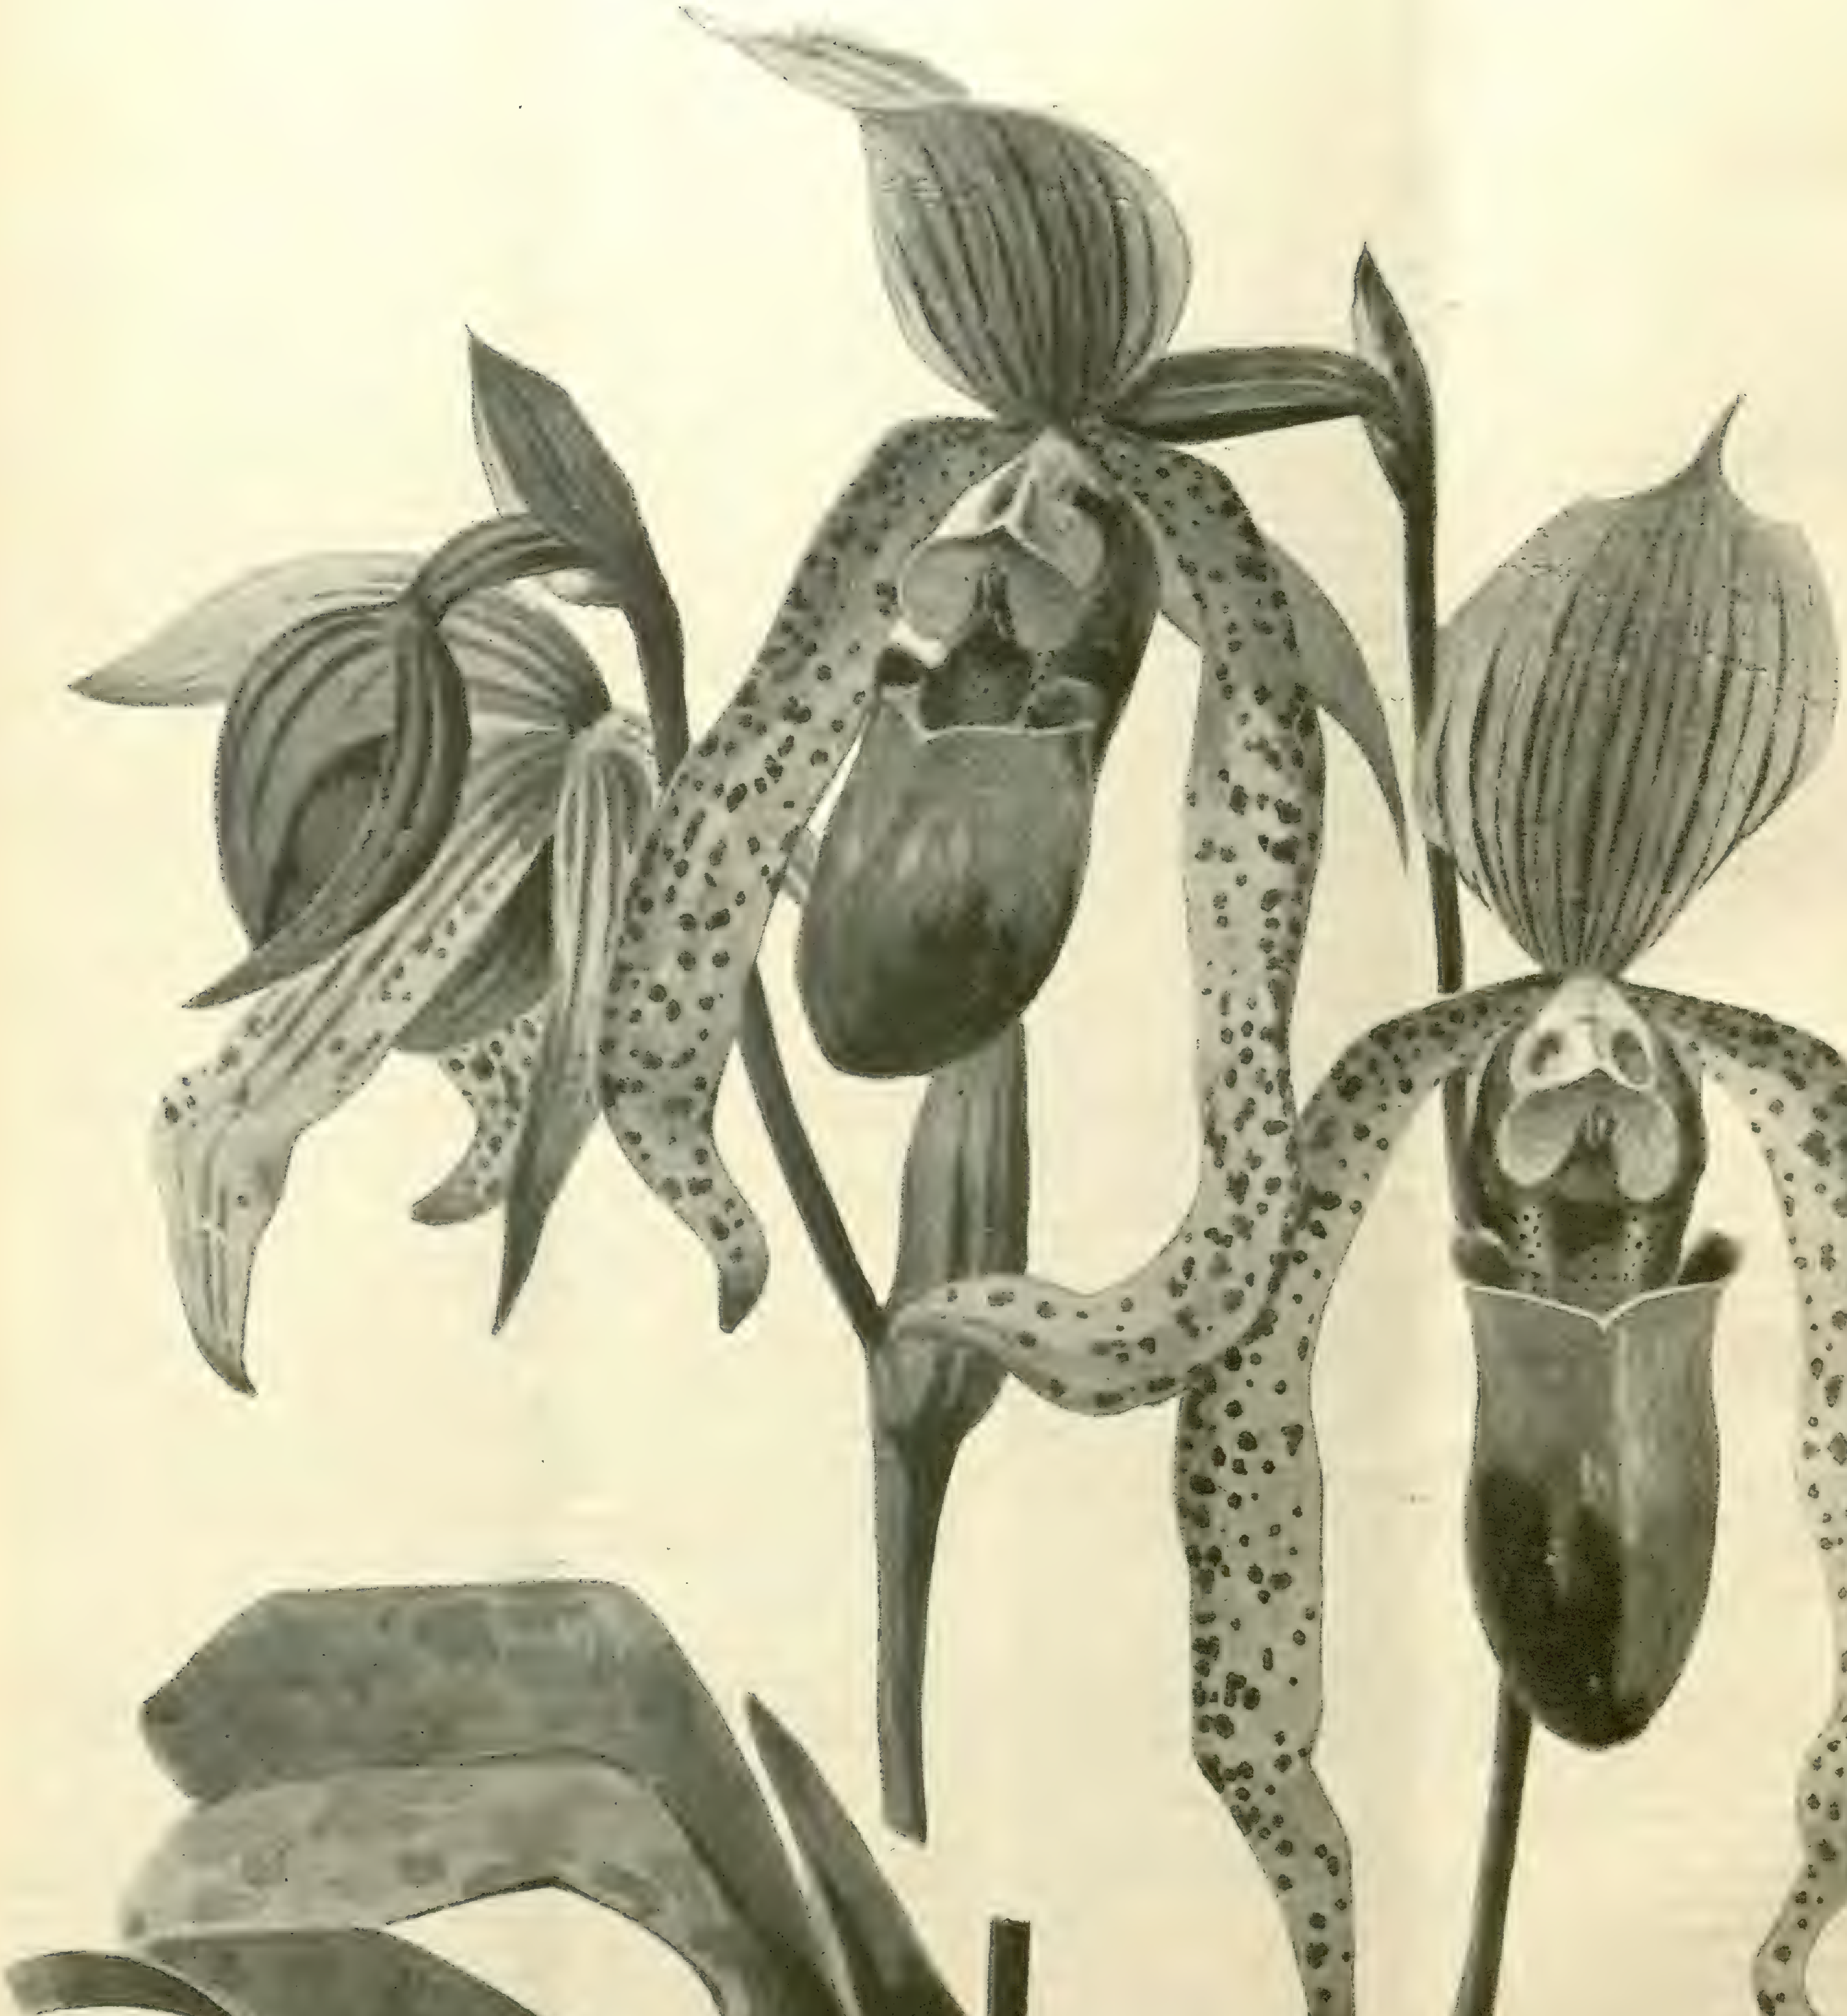
With such a mild winter as we have had, spring cabbages promise to be earlier than usual, and I fear in some gardens there will be many losses from "bolting," as recently I saw several quarters that had already suffered in this respect. For many years I, in common with many others, lost a good portion of our spring crop by premature flowering, but there are few losses now, owing to our different mode of culture. Many growers are far too kind to the plants, for it is a common practice to place large quantities of rich manure under the roots of small plants, and the result is a soft growth that bolts after the least check. Some of our older varieties are much addicted to "bolting," and it is not well to rely upon these for the earliest supplies; many are large, and suffer more from cold than smaller kinds, So far I have not met with any variety equal to Ellam's for earliness and stability. Many market growers have excellent varieties of their own selection, but they grow larger kinds than Ellam's. The latter is too small for their purposes, but on the other hand, the market stock for spring supplies is grown in suitable soil in the open field, and less subject to disease than on old garden land, so that there is less "bolting" than in soil much manured.

My plan to prevent running will not commend itself to all, but it has this merit, that we have few failures and little anxiety as to our crop. We do not manure the land at all when planting, yet many think quarters for spring cabbage cannot be too rich; we did manure formerly, with the result that we lost a goodly portion of our crop, and this made us adopt other measures. Seeing what good results followed the planting of broccoli on land which had produced a crop, and not dug or otherwise prepared, we followed the same plan for early cabbage, and now rarely lose one per cent. from any cause. Our cabbages follow the spring [illegible] onions, and having a light soil we tread and roll the land for the [illegible] crop, and this frequent working upon the land makes it as hard as possible; the surface is lightly hoed over after the crop, and the cabbages put out the latter part of September, or earlier, according to the season. Drills are drawn to prevent the moisture given when needed running away. The roots are firmly trodden in when planted, and the result is that there is a short sturdy growth and no bolting.

Mein's No. 1 is equally satisfactory as regards growth as Ellam's but the latter is a little earlier, and this is a gain; as in such a season as this spring cabbage will be most valuable, for all green stuffs will run to flower so quickly that green vegetables in April will be none too plentiful. In hard winters soil is drawn close up to the plants in [illegible]ber, but previous to doing this each plant is made firm, our aim being a sturdy hard growth. One can easily feed later, and we are now feeding our cabbages with a fertiliser in showery weather; the result is [illegible] marked in a few days after giving the food. I believe in feeding when the growth is active, not when the plants are too small to benefit by it. To show how early the season is, we shall cut freely after the first week in March, as the cabbages are growing as freely as in April.

G. Wythes.

Syon Gardens.



CYPRIPEDIUM SANDERO-SUPERBIENS. (Flowers white, greenish yellow, and brown.)

VEGETABLES FOR EXHIBITION.

MAINCROP POTATOS.

MANY kinds of soil will produce first-rate potatos, but without a doubt a good light mellow loam is the most suitable. For quality and flavour, a chalky kind of land is well adapted and perhaps the very worst for their culture is a stiff heavy clay. In wet, sunless seasons, the tubers produced in strong clay soils are almost worthless for eating, as well as being very liable to disease. Good potatos can now be purchased at very reasonable prices, so that it is much better to buy seed and use the ground, when unsuitable, for other crops. Change of seed and the selection of suitable varieties must always occupy the mind of the grower. There are now so many good varieties in the market, and it is worth remarking that they differ materially in their adaptation to various districts. Thus the cultivator must endeavour to ascertain which are best for the locality in which he resides. The land should be deeply broken up during the winter and potatos ought not to be grown on the same piece of ground two seasons in succession, a most important point in potato culture. In preparing the ground one must take into consideration the nature of the soil, which should never be made too rich. If there is a good depth of soil and it has been manured the previous season for other crops, no manure is necessary. The same applies to fresh broken-up rich pasture land, but on poor shallow soil, whether it be chalk, gravel, or sand, a thorough good dressing of fresh stable manure should be given when preparing the ground.

We are so much at the mercy of the weather during spring that no hard and fast rule can be laid down, and the nature of the ground one has to contend with must always be taken into consideration. Plant, however, when possible, from the middle of March to the middle of April, but in any case endeavour to plant when the land can be left in a light and workable condition. The sets for planting should be of medium size, leaving only from two to three sprouts on each, but when from any cause large ones have to be used, they may be cut leaving two sprouts on each. When cutting tubers for planting it is a good plan to dip the cut parts in slaked lime, allowing them to dry before planting. The sets should be laid out thinly in a light place just secure against frost during winter, thus conserving as much strength as possible. When laid thickly in heaps the shoots become so long and spindley that they have to be rubbed off, and much of the food reserve is wasted. The distance which the rows and tubers should be apart must be determined by the sorts one is about to plant, as the haulm of some varieties requires double the space than that of the others, and much of the failure in potato culture is due to overcrowding. From two to three feet is a fair average distance to allow between the rows and from eighteen to twenty inches is desirable between the sets.

Between the time the young tops peep above the surface and the time for moulding up the soil should be flat-hoed twice, and as soon as high enough no time should be lost in earthing them up. Except to pull out any weeds that may make their appearance the crop may be left till ready for lifting, which should be done without delay in fine weather as soon as the skins are set. Many potatos, I am certain, become spoilt by being left in the ground longer than is necessary.

Choose fine weather for this operation, and first cut off the tops with a hedging hook, and burn them. Carefully lift the crop with the potato forks and search the ground thoroughly so that but few, if any, tubers are left, as tubers that are left cause a good deal of trouble in the following year. The tubers should all be laid out to dry on the surface of the ground, putting three rows together, and the roots and rubbish should also be put together in rows, so that they may be easily removed and burned as soon as the crop is cleared off. Only lift each day as many roots as can be stored under cover. When one has to depend on samples for exhibition from the main plantation (and in some soils good, clear, well-shaped tubers can be grown) the very best should be selected as they are turned out, and immediately placed in baskets or boxes, which should be kept covered with an old sack, or even paper, to exclude the light and air, and the same day they should be placed in boxes one layer deep only, and covered up with some finely-sifted, moderately dry soil, and placed away in the dark in a safe place till wanted.

In storing the crop, commence by taking up all the largest and best tubers suitable for cooking, and place them under straw covering in good heaps, where they may be left for about three weeks. Subsequently they should be carefully examined for any diseased tubers (a very suitable work for wet days), and then finally stored away till wanted. In my opinion, there is no better way of keeping potatos than pitting them in clumps in the open, taking out a sack or so at a time according to requirements, and keeping them in some easily accessible place. Select a dry, well-drained spot, slightly raise the ground on which the clamp has to be made, so that no water may reach it, and over this place a layer of dry straw. On this layer put the potatos, building them up ridge shaped. A good coating of straw should then be packed over them, and this in its turn must be covered with about six inches of soil. It is also desirable to have about every four yards a tuft of the straw rising through and above the soil at the apex. This will prevent over-heating and keep the crop sweet. In very severe weather some litter should be thrown over the ridge, the quantity being determined by the severity of the weather. A little cover keeps out much frost.

The sets, or "seed" for planting should next be attended to. They should be taken in and laid out thinly, and if allowed to become green they are all the better for this purpose. A cool building, just proof against frost, is the most suitable place for wintering them, and when room can be had I advise keeping them on lattice shelves in single layers, using the utmost care to keep the different kinds separate. Examine them at intervals during the winter, removing any [illegible] and rub off the chits if by any chance they have commenced [illegible] too soon, and they will be safe till the time of planting. Attention [illegible] be given to the tubers that are considered worthless for seed. These should be picked up and used, for they make excellent food for [illegible] poultry. The ground should then be cleared of all rubbish [illegible] tubers, which should be burned, and the ground left in a neat [illegible] state.

Only a favoured few who are fortunate enough to have an ideal [illegible] soil can hope to obtain such splendid specimens as are often seen on the show tables, unless some special means are taken to produce them. Here on a stiff, wet, London clay it is absolutely impossible to have well shaped, clear potatos by ordinary cultivation. Hence some special treatment must be given to them. I have made numerous experiments, and was much puzzled for many years before I could ensure satisfactory results. I tried the best varieties, different times and modes of planting, and many kinds of mixtures in the way of compost, but the result generally was disappointing. Notwithstanding, I was determined, if possible, to continue until I satisfied myself, and I can now say I have done so. I consider the principal points are an open sunny position, a well-drained piece of ground, early planting, allowing plenty of room between the rows, and tubers, and the mixture for planting [illegible] The ground should be thoroughly trenched during winter, and at the bottom of each trench a coating of about four inches of long stable [illegible] should be given, leaving the surface rough and uneven, thus allowing the frosts and winds to thoroughly pulverise the soil. Early in March the planting should be done. Prepare a mixture of half-decayed horse manure, that from an old mushroom bed is preferable to any other, and half good leaf-mould. This should all be passed through a sieve with half-inch mesh, and thoroughly mixed. A good trench should be taken out with the spade at least a foot in depth, and in this should be [illegible] about six inches of the mixture. Assuming the sets have been properly prepared as previously advised, these should be carefully laid on the soil at a distance of two feet apart. Fill up the trench with the same kind of mixture, and over this draw a little of the finest of the soil taken from the trench. Neatly rake over and make a mark down the centre. The distance between the rows should be three feet six inches; it will be found far better to thoroughly cultivate a few rows than only half prepare a large number, as it will be found that a very large percentage will turn out fit for the exhibition stage. If horse manure cannot be readily obtained pure leaf soil will answer almost as well. Hoe the crops frequently and thoroughly, protecting them if necessary, and earth up as soon as ready. When the haulm has grown a moderate height and is likely to fall down it should be kept in an upright position by driving in a few stakes each side of the row and stretching two or three stout lines of string along. This is a very neat and efficient way of keeping them in position, and I consider it of the utmost importance. As soon as the growth is completed and it is safe to lift the crop, cut off the tops and lift without delay, carefully storing as before advised.

In my opinion potatos are generally exhibited much too large, [illegible] long as exhibitors have to cater for judges who favour large tubers, so long will large specimens continue to be staged. I consider a potato should be of medium size, shallow eyed, free from scab or cracks, and the skin quite clear but not necessarily smooth, as a roughness in the skin generally denotes good cooking qualities. They should be washed thoroughly clean on the afternoon before the show in soap and water with a piece of soft sponge, and as soon as dry wrapped in clean soft white or brown paper. Care should be taken not to expose them to the air more than is necessary or much of the fresh appearance will be lost. Six or nine is the number generally shown, and they should be presented as even in size as possible. There are now so many first-rate kinds in existence that I shall not attempt to give a lengthened list of varieties as soils and localities have so much influence on particular kinds. What proves to be everything that can be desired in some parts of the country is absolutely worthless in others. However, I will mention a few [illegible] types as a guidance. For a collection of vegetables I always favour [illegible] white skinned variety, and I like the pebble shape. For early shows I advise Sharpe's Victor or some good strain of Ashleaf, and for summer and later exhibitions such kinds as Snowdrop or Windsor Castle. The latter is a great favourite with me, and though not one of the largest it is [illegible] handsome, and of the highest quality when cooked. This, I think, should be taken into consideration by the judges equally as much as in judging fruit. Probably the most handsome potato ever raised is International, and it looks extremely well when shown, but for table use on nearly [illegible] soils it is worthless. Satisfaction is a splendid exhibition potato, and perhaps exhibited more than any other variety. It is of very fine quality from many soils, but it is often staged too large. Goldfinder and Triumph are also well worth growing. Of white rounds Schoolmaster is fine in every way, but unfortunately very subject to disease. [illegible] the coloured kinds, both round and kidney shaped, are very handsome and pleasing to look at, and must be cultivated when it is the intention of the exhibitor to enter for potato competition, but as a rule the highest quality will be found in the white-skinned kinds.

Aldenham House Gardens, Elstree, Herts. E. BECKETT.

The Distribution of British Mosses is a matter which Mr. [illegible] Horrell, Brompton Square, S.W., wishes to see cleared up, and he [illegible] invites the co-operation of bryologists to work it out. Watson divided [illegible] Britain into one hundred and twelve vice-counties for the purpose of [illegible] better understanding of the distribution of flowering plants. Mr. Horrell, [illegible] on the same principle, has fairly good lists from about fifty vice-counties; [illegible] remainder there are offers of assistance from only thirty-four districts. [illegible] H. N. Dixon and E. M. Holmes have promised to examine doubtful or [illegible] species, so that with a little more help the work Mr. Horrell has taken up [illegible] go forward.

WORK FOR THE WEEK.

WARM ORCHIDS.

PHALÆNOPSIS Schilleriana, P. amabilis, P. Sanderiana, P. leucorrhoda, P. grandiflora, P. Stuartiana, and others that have finished flowering will now require attention; all the old material must be very carefully picked out of the baskets, cylinders, pots, or blocks, and well washed out in a pail large enough for the purpose, or with the watering can. Make sure all the small beetles and snails are entirely eradicated. After this take fresh sphagnum, well picked and washed through clean water several times, together with some nice pieces of charcoal about the size of a walnut, except at the bottom, where larger pieces will be required; a hard blunt, pointed stick will be found very useful to place the charcoal and sphagnum in with. Every care must be taken of the roots that are firmly attached, and also of the points of those that are just pushing out. A few clean crocks will also be found very beneficial. Placing them here and there with the charcoal and sphagnum, a good plan is to put a piece of red sandstone underneath the new roots, as they soon adhere to it. Any that require new baskets or cylinders —the latter, in my opinion, being far the best—must be carefully handled, and a sharp knife used, cutting away the wood along with the roots. After this work has been done, the shading will require particular attention, otherwise the foliage will lose vigour and appear limp. A slight syringe occasionally must be given, and a nice humid atmosphere be carefully maintained. Of late we have witnessed some very treacherous weather, such as registering 11 degrees of frost, cold winds, hail, snow, and cold rain, which is very trying for growing orchids. Moreover, we have had hot sun in the middle of the day at times. At such times a little shading must be used, if not the leaves turn yellow; a very coarse blind is the best now, and the thicker ones as the season advances. Firing and ventilation must be carefully studied.

Vandas of the suavis and tricolor section must be top-dressed or repotted as required; clean crocks, charcoal, and fresh sphagnum being the right material to use with the pots well crocked. Leggy plants must be cut down and lowered to the base of the leafy stem, in order to have bushy plants; a slight syringe occasionally, taking care not to syringe overhead, will help to keep the foliage fresh. Saccolabium Blumei giganteum and others may have the old material picked out of the baskets and replaced with new, care being taken of the roots. Dendrochilum glumaceum, as soon as the flowers are over, must receive immediate attention if necessary; baskets are the best for it, using fibrous peat and sphagnum as material. Cattleya aurea requiring more room must also receive attention; baskets are far the best for it. Imported cattleyas that are beginning to root must have the crocks removed about them, and fibrous peat substituted. Unflowered cattleya and Lælio-cattleya seedlings must be repanned or rebasketed, and suspended from the roof in a house by themselves. Old specimens of Cattleya Mossiæ and Mendeli that are nearly worn out must be pulled to pieces, the smaller the better, and well washed with weak soft-soap water. If too far gone, and the variety is choice, it would be the better plan to place these divisions in crocks, and treat them exactly as imported plants. Selenipediums, such as S. calurium, S. Ainsworthi, S. cardinalis, S. Sedeni, &c., may be split up, and if a stock is required, they can be pulled to pieces to the desired size. A good compost consists of equal parts of good peat and loam, with a little charcoal, old mortar, and sand. The earliest plants of Dendrobium phalænopsis must be potted if necessary.

Damping down must be done twice a day, according to the atmospheric conditions outside. The general stock must be well examined for thrips and all pests. If the blinds are not in readiness, they must be put in order at once.—T. STAFFORD, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE.

IN many gardens where palms are used frequently for indoor decoration this often interferes with repotting them at the proper season. As these will not be required for some weeks for the prupose mentioned above, we are taking the opportunity of examining the stock, and either giving larger pots or tubs to those requiring it, or surface-dressing others. These plants are less liable to injury when used in dwelling rooms if they are somewhat pot-bound, providing the roots are regularly supplied with water, than is the case when they are over-potted, as the soil is apt to become sour and the roots decay. Still it becomes necessary at times to afford slightly larger pots, though with the view of using these as small as possible many of the lower and coarse roots may be reduced, providing the plants are in a healthy condition. A few kentias, from five to six feet high, growing in 7-inch pots, have proved most useful; but it was decided to give them larger ones this spring. We found, as we expected, very little soil left in the pots, which were filled with white, fleshy roots, proving what a length of time palms may be sustained on almost moisture alone. Rich, turfy loam, sharp sand, with a free addition of fine charcoal forms a good compost for palms, dracænas, and other greenhouse foliage plants, the charcoal mixed with the soil being necessary to ensure drainage and keep the material sweet. A close, humid atmosphere, a shady position, and frequent syringing is very necessary to newly potted plants of this description. The green-leaved dracænas, such as D. indivisa, are most useful and ornamental, even when they have lost their lower leaves, as after they have become tall they form good centres for groups, and they also give a sub-tropical effect to the pleasure grounds during the summer when the pots are plunged in the turf. After a time, however, these become too tall for the conservatory, and the present is a good time to arrange for striking the tops; in doing this, the thicker the stems the deeper must be the incision. A good wad of ground moss bound round the cut kept constantly moist will soon induce a mass of roots to appear; but care must be used not to sever the tops from the stem until sufficient roots are secured to sustain the foliage. After the tops of these plants are rooted in this way, a close atmosphere with plenty of moisture is necessary to encourage free growth. Ficus elastica is both useful and ornamental when the stems are clothed with healthy leaves, but any which have lost their foliage should have the tops taken off, placed singly in small pots, filled with sandy soil, and plunged in a brisk bottom heat. Now is a good time to divide and repot Isolepis gracilis which forms a pleasing margin on stages or to groups. Where five or more cuttings of crassula were placed in small pots in the autumn these will have become well rooted and should be shifted into larger pots. Larger plants which are to flower this season should be kept cool and near the glass, or they will grow tall, which is a disadvantage; the pots being filled with roots, liquid manure water may be used directly the flower trusses become visible. Abutilons are useful, especially those with variegated foliage, either for the conservatory or flower beds, and a batch of cuttings put in now will furnish neat plants in a few weeks. Graceful table plants may be obtained by inarching A. vexillarium on to A. Thompsoni with stems two feet or more high. Aspidistras should also receive attention in the way of dividing and repotting where necessary, before new leaves push up; these are most valuable for standing in shady corners, or under taller plants, also for use in dwelling rooms; small pots and sandy soil favour neat variegated foliage.

Cytisus racemosus will soon give a display of brilliant yellow and fragrant flowers; but these lose much of their beauty when the foliage is not of a dark healthy green. Copious waterings are necessary, or the leaves are apt to fall wholesale, while liquid manure once or twice a week will prove of much assistance. Epacris in variety as they go out of bloom should have their shoots shortened back, and be stood together where they can be sprayed overhead; and water sparingly until new growth commences, and then those requiring it may be repotted. Peat, coarse silver sand, and firm potting is necessary. Hydrangeas will produce large heads of bloom in very small pots if the roots are kept well supplied with nourishment. Cuttings struck in sixties last September may be be potted into forty-eights. Give them a rich compost, and place near the glass in a warm frame or greenhouse. Lilium Harrisi will be of great service for Easter decorations, therefore directly the plants show flower, fumigate them, and if placed in a temperature of about 60 degrees, they will come on quickly. It is a mistake to force these plants before the flower-buds form, as they become tall and weak. A surface dressing of rich compost, together with the use of liquid manure will assist to develop fine flowers if afforded early after buds appear. Introduce batches of spiræas, azaleas, lily of the valley, and other things into heat by degrees to maintain brightness in the conservatory, and provide suitable flowers for cutting. Keep vessels containing seedlings well up to the glass, and lose no time in pricking these off directly they are large enough to handle. Push forward the work of propagating all plants that are likely to be required, both for decorating and bedding purposes, and make provision for sowing many of the half-hardy annuals in pans, boxes, or on gentle hot-beds, which must receive attention between now and the end of the month.—RICHARD PARKER, *Goodwood Gardens.*

THE FLOWER GARDEN.

THE planting of new herbaceous borders may be carried out at the present time, or as soon as the soil is in a condition to work upon. Lists of suitable plants have often been given in these columns, therefore it is unnecessary to repeat names here. In planting avoid straight lines of plants; the tallest growing must of necessity be planted at the back of the border and the shortest in front, but this should not be carried out too strictly; for instance, if plants of medium height be associated with those of taller growth, an undulating outline is obtained, and a breaking up of the flatness or formality otherwise apparent. Many subjects may be propagated now for these borders. Varieties of Michaelmas daisies may be easily increased for planting out a little later on. I find the most convenient method is to take off the side growths or suckers, which are by this time mostly emitting roots, and pot them up into five-inch pots, placing four or five in each, afterwards standing them in a cold frame for a few weeks, by which time they will have become strong clumps for turning out into the borders. These extremely useful autumn-flowering plants are deservedly becoming popular, and whether for border decoration or use as cut flowers, a dozen at least of the best varieties should be grown. For massing, too, some of the dwarf and tall varieties are admirably adapted, and when so used are most effective, such, for instance, as A. amellus bessarabicus growing about two feet in height, and producing an abundance of deep-violet coloured flowers, or A. Nova Belgi Robert Parker, which grows to the height of four to five feet, giving an abundance of sprays of lavender-blue flowers with a yellow centre. Other desirable sorts are A. acris, lilac purple, two feet, early; A. lævigatus, two to three feet, flowers rose-coloured, of compact habit; A. Harpur Crewe and A. Purity, both white flowered, tall, five feet; A. Nancy, pale blue, four feet, good; A. cordifolius Diana, four feet, produces graceful sprays with masses of soft lavender flowers; A. ericoides and A. diffusus horizontalis, handsome small-flowered varieties, three feet; A. Maia, fine large rosy lilac flowers, four feet; A. Tradescanti, a late-flowering species, producing numerous small white flowers on graceful sprays. The deep-green, finely-cut foliage of the last mentioned is handsome, and shoots of this alone are useful for mixing with other cut flowers, and I may here remark that plants of this, grown in pots, form very useful decorative material for the conservatory in October and November. The Michaelmas daisies are so numerous that a small selection is somewhat difficult, but the dozen mentioned give a long succession of flowers, and during the past two years A. Tradescanti has been very good in the open in November. Border chrysanthemums should be increased by cuttings, either for planting out in the herbaceous borders or the reserve garden.

Carnations, growing on outside borders, should have the surface soil stirred about them when in a sufficiently dry state to work easily and the plants be pressed into the ground firmly. Spring bedding plants of all kinds should be similarly treated. Carnation plants wintered in cold pits and frames should be kept well exposed, with a view to planting out as early as possible. The ground should be in good condition, and if convenient, a change in site should be given annually. Calceolarias struck in autumn and wintered in cold frames should have full exposure, unless frosty, pinching out the points of the shoots to induce bushiness. These will shortly need transplanting into cold pits or in a position where they may be protected from sharp frost should such occur. Where flower beds are empty, those intended to be filled with calceolarias may shortly be planted and provided with a temporary shelter of fir branches or other material until partially established, or in the event of frost occurring; when thoroughly hardened a few degrees will do them no harm. Stores of gladioli should be examined, and any decaying corms removed. Some of the commoner and early-flowering varieties as Brenchleyensis may be planted forthwith; the varieties, Colvillei and C. alba are also useful for furnishing cut flowers, and require planting early. Mild hot beds are necessary for the raising of annuals in quantity, and these should now be made up Two parts of leaves, to one of strawy stable manure, will make a suitable bed if built from three to four feet in height, to be trampled firmly while building. After placing on the frame and partially filling with leaves, finish off with three or four inches of sifted light soil, that when finished it shall be four inches from the glass; put the lights on and allow to remain for a week or two to become warmed through. The pruning of roses may be taken in hand with safety now. For garden roses, strong growths may be pegged down, while H.P.'s for exhibition blooms should be pruned-in to two or three eyes. Teas should have all weak growths cut back close, allowing the stronger to remain at considerable length.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUITS.

SINCE penning my last notes we have had a sharp spell of winter weather which has checked the all too forward growth in this department. I advised coverings for apricots, and peaches will now need similar treatment, though I place much faith upon a good coping, as this throws off rain, and the mischief is usually caused by frost when the blossom is wet. Pruning and nailing of peaches should proceed, as there is no gain in keeping the trees from the walls when the colour of the bloom can be seen, and as soon as this work is done it will be advisable to give protection. The grower's attention will be needed in the gooseberry and currant quarters, as small birds are most troublesome. I have advised the use of quassia extract and fresh lime, as this is not at all relished by the birds. Many growers leave their bushes very thick with wood in case birds are troublesome, but it is not a good plan. Gooseberries on walls are most useful for late supplies ; such trees should have a good portion of old spur growth removed as they attain age or size, as if all are left small fruits will follow. Gooseberries grown as cordons are most profitable, and they are readily managed and protected. Doubtless this is the best way to grow the large Lancashire varieties, as in the open their quality is superior, and the fruits keep much longer than on bush trees. There are various shapes, from the single to the four-stemmed cordon, and for the latter posts and wire will make an efficient trellis. Now is a good time to give these trees good surface dressing, and I find a liberal top-dressing of guano or fish manure now, whilst the trees are bare, is soon washed to the surface roots, and does much good. There is a saving of space when bush fruits of any kind can be grown as described, and in some gardens such trees may with advantage form the division between the fruit and kitchen gardens, or be made use of as a screen. Vines are often grown against buildings, and with a favourable position fruit may be had of fair quality. Now is a good time to thin out old growths and lay in new wood ; to obtain fruit, there must be ample space. For the last few seasons we have had good fruit on an east aspect. It is a good plan to cut out a fair portion of old spurs and bare wood at this pruning, and, if possible, give the roots a dose of liquid manure.

Raspberry canes may now be cut to the required length and made trim for bearing, and the same remarks are applicable to blackberries. In the case of the former avoid crowding, for, as a rule, far too many canes per stool are left. We always give our bearing canes a good mulch of decayed manure at this season, having a light soil to deal with. Newly-planted canes may now be cut to within six inches of the soil, and it will be a mistake to let them bear fruit or flowers. Canes for autumn fruiting, of such kinds as Belle de Fontenay and October Yellow, should also be cut down to the soil, and depend on the new growth for late fruit. We find Superlative will give very late fruit if grown on a north border, and the canes cut much shorter than is the usual practice. Strawberry quarters will now need cleansing, as they are often left from last September, or even earlier, and weed growth will be troublesome. The plants started into growth very early this season, and some of our summer-planted set, had prominent spikes, but fortunately frost has checked growth before it was too far advanced. Give food to the old plantations, and prepare others for cropping. I am not in favour of digging between the stools ; if it is necessary to renew the surface, this is best done by using a fork, and just burying weed growth. With young plants in light soils, it may be well to tread round each previous to the cleansing process, as loose plants will be the first to suffer from drought. Now is a good time to give a mulch, as then the plants make new surface roots freely. Royal Sovereign grown as an annual will not need food if the ground was prepared well, and here a mulch of short litter will suffice, as this will be bleached and cleansed by exposure, and in condition for the fruits to rest upon, and also be useful to protect from frost and drought. Many growers being obliged to resort to spring planting, and having secured late runners for the purpose, there should be no delay in carefully planting them out. Should the weather be dry, a little litter up each side of the rows will assist growth and arrest drought. Now is a good time to raise alpine strawberries from seed sown in a warm frame ; keeping close to the glass, and pricking out the seedlings in a few weeks' time in good soil in a sheltered border. Many plant runners from last season's plants, and by so doing obtain fruit in advance of those from seed.—G. WYTHES, *Syon Gardens*.

Seaweed in the Garden.—Seaweed has many uses in the garden, and those who are near enough to the coast to secure it should not despise it because it is common there. To begin with, it comes in very useful for throwing over celery in winter in order to protect the tops from frost. Then it affords an admirable top-dressing for asparagus beds, affording a little protection to the crowns, and likewise furnishing them with a little salt owing to the rain washing through the weed, and salt is very good for asparagus. A covering of this in winter and a dressing of wood ashes early in spring will be found to do more good than the rank manure often used, which has a tendency to cause the heads to come crooked. Near the seaside a great deal of seaweed is carted on to the land. A very good plan of dealing with it is to stack it in heaps like turf, but with a layer of old manure, garden refuse, or road scrapings between each six-inch layer of the seaweed. This makes a very useful fertilising heap, which may be drawn upon with advantage for most crops. The seaweed should not be kept too long, as when quite black and decayed its odour is very offensive.—W.

Economic Botany in the West Indies.—The West India Royal Commission appointed to investigate the sugar industry and propose means for the improvement of the West Indian colonies, assert in their report that one of the means to the end in view would be the establishment of a department of economic botany in the West Indies. The Royal Commission states that the botanical establishments in the larger colonies, such as Jamaica, Trinidad, and British Guiana, have already rendered considerable assistance in improving agricultural industries, and they are capable of being made increasingly useful in this respect. In the Windward and Leeward Islands and Barbadoes, small establishments called botanic stations were established a few years ago on the advice of the Director of Kew Gardens, and the results, though not yet extensive, have been of a distinctly promising character. It is evident that to grapple with the present circumstances, there is required for the smaller islands a special public department capable of dealing with all questions connected with economic plants suitable for growth in tropical countries, and we recommend the establishment of such a department, under which should be placed the various botanic stations already in existence. These stations should be enlarged in their scope and character, and be organised on the lines found so successful in Jamaica. In the latter colony it is admitted that intelligent and progressive action in the direction of encouraging a diversity of industries has produced most satisfactory results. To achieve this result has, however, taken more than twenty years of persistent effort, and the Government has spent more than £100,000 during that period on its botanical establishments. The department has distributed seeds and plants at nominal prices by means of the post office, Government railways, and coastal steam service ; it has supplied information orally, or by means of bulletins, regarding the cultivation of economic plants, and has encouraged the careful preparation of the produce by sending agricultural instructors on tour through the island to give lectures, demonstrations, and advice. The special department recommended for carrying on similar work in the Windward and Leeward Islands should be under the charge of a competent Imperial officer, whose duty it would be to advise the Governors in regard to all matters affecting the agricultural development of the islands. He would take part in consultations with the object of improving agricultural teaching in colleges and schools, and of training students in agricultural pursuits, and would attend to the preparation of suitable literature on agricultural subjects. The existing botanic stations should be placed under his supervision, and the charge of maintaining them transferred to Imperial funds.

LITERATURE OF PLANT NAMES.

from [illegible]

IN the course of an interesting contribution to *The Guardian* on the gardener's library, the writer says with reference to those in which plant names receive prominent attention :—

It is pleasant to note that among these many books those written by English authors hold a very prominent place. From the time of Elizabeth to our own day there have been authors who have taken plant-names for their subject, and have written on them with much learning, and very pleasantly. The lead is taken by William Turner, who, in 1548, published "The Names of Herbes in Greke, Latin, English, Duche, and Frenche, with the commune names that Hebaries and Apotecaries use." This is a scarce little book, but was reprinted in 1881 by the Early English Text Spciety, well edited by Mr. Britten. Turner led an eventful and troubled life, and died Dean of Wells ; he wrote many books and travelled much, and in all his travels and troubles his love for natural history was constant, and he was held in high esteem by the great botanists of the sixteenth century, and was much consulted on other parts of natural history, chiefly on birds and fishes. But his books on plants are probably the only ones now read, and with one specimen of his treatment I will leave him. The volume of "The Names of Herbes" begins with Abies :—

"Abies is called in Greke Elate, in English a firre tree, in Duch Emdannen, in French Sapin ; it groweth in the Alpes naturally, and in certeyne gardines plāted and set by mannes hands boeth in Englande and in Germaine."

Gerard must be considered the second English author who did anything for plant-names, though the main object of his great volume was the description and cultivation of plants. With all his many faults and inaccuracies, we owe much to him (though still more to Johnson, the editor of the second edition in 1636) for his diligent search for plants of all sorts, which he cultivated with great skill. In his description of each plant there is a special section for the names, which are given in Greek, Latin, French, Italian, Dutch, &c. At the end of the book is "A Table of such English Names as are attributed to the Herbes," followed by "A Supplement or Appendix unto the General Table, and to the Table of English Names, gathered out of antient written and printed copies, and from the mouthes of plaine and simple country people," and by "A Catalogue of the British Names of Plants, sent me by Master Robert Dauyes, of Guissaney, in Flintshire." By British names he means Welsh names, and the three lists together are the best lists of English names of plants that we have up to the end of the sixteenth century. In 1629 Parkinson published his "Paradisi in sole Paradisus Terrestris," and paid special attention to the English names. About the same time John Ray, one of the most distinguished of English naturalists, who almost anticipated Linnæus in his scientific arrangement of plants (but the time was not ripe for it), published his list of plants growing in Great Britain with a particular account of the names. In 1650 we have the "Etymologicon Botanicum" of S. Skinner, forming an appendix to his "Etymologicon Linguae Anglicanae." It is a full and interesting account of plant-names derived from twelve languages ; but his derivations are fanciful and not trustworthy, as when he says that stock-gilliflowers are so called because both root and stock are as firm and hard as wood, which certainly they are not. A much better book, though not by an English author, is Mentzel's "Index Nominum Plantarum Multilinguis," published at Berlin in 1682, which gives good information about the plants in a small compass and a copious list of names ; *e.g.*, he gives the names of crocus in Latin, Greek, Italian, Spanish, French, English, German, Belgian, Danish, Bohemian, Polish, Lithuanian, Arabic, Indian.

From the end of the seventeenth century till almost the middle of the present century, there is no English book specially dealing with plant-names. Now there are many books on this interesting subject, among which a high place of honour must be given to Dr. Prior's "Popular Names of British Plants." The first edition was published more than thirty years ago, and was soon followed by new editions ; and the book is indispensable to any one who wishes for a scientific account of the names, being far in advance of anything previously published on the subject. The introduction is especially worthy of study, for it contains a masterly account of the many different sources from which our plant-names have been derived. But it was confined chiefly to book names, and took little or no notice of local names, and very little of any common names except those of British plants ; and so something more was required, which was supplied by Messrs. Holland and Britten's "English Plant Names," published in 1886 by the Early English Text Society. Too much can scarcely be said in praise of the care and labour spent on this book ; all local names have been collected and all English names that have at any time appeared in books, except those which are only translations of Latin names and do not pretend to be more. Authorities are given for every statement, and occasional notices on the history of the names, never lengthy and always to the point. In this respect it compares very favourably with another book, Miller's "Dictionary of English Names of Plants," published in [illegible]. This is a long list of names, and that is all ; any and every name has been admitted that could be found anywhere ; no authorities are given, and many of the names are in no sense accepted names, but are either bare translations of the Latin or new inventions of the author and his friends. As a list of names it has some little value, but none beyond that. Professor Earle's little book, "English Plant Names," published in 1880, stands on a very different level. It is confined to the names which occur in the old glossaries to the end of the fifteenth century ; but of those it gives a very complete account and explanation, and the lists are introduced by a scholarly preface, which traces the history of English plant names from the earliest times ; and throughout the little book Professor Earle's great philological knowledge is brought to bear on our English names in a way that makes us feel we can thoroughly trust him, and makes us wish that he had given us more. A still later book, Alcock's "Botanical Names for English Readers," is a popular book, but it is not easy to say why it should be so. It is confined to the scientific names of British plants, of which it professes to give an explanation ; but there is really nothing in it that has not been already given in every good British Flora, especially in Hooker's "Student's Flora," and Syme's edition of Sowerby's "English Botany." The author, however, is far bolder than Hooker or Syme, for, where those authors are content to say of a name that its etymology is doubtful or uncertain, Mr. Alcock has no doubt or uncertainty, and some of his derivations are marvels of boldness. When, for instance, an author attempts to explain the Greek and Latin names of plants and tells us that *aira* (a Greek name used by Aristophanes for some grass or weed) is from "Gk. *airo*—to take because of its injurious effects ;" that *hippuris* is from "Gk. *hipp*—a horse, and *oura*—a tail ;" and that *hellebore* is from "Gk. *hele* (*helein*)—to take away or remove, and *bora*—food," we can only pity those who take him for a guide.

There are many other books more or less connected with English plant names. Comber's "Etymology of Plant Names" (1876-7) is a satisfactory account of the names of "fruits and edible berries, kitchen vegetables, and salad plants," but is confined to these. Cameron's "Gaelic Names of Plants, Scottish and Irish" (1883) is an interesting account of the native names given to the plants of Scotland

land and Ireland, which in no case seem to have any connection with our English names; and he speaks with approval of Gerard's list of Welsh names, already noticed. And not only in England, but in almost every civilised country books have been published on plant names. Some are complete dictionaries, or profess to be so, as J. and W. Grimm's "Deutsches Wörterbuch," Nemmich's "Nomenclator Multilinguis," Ulrich's "Internationales Wörterbuch," in which the names are given in Latin, English, German, and French; and the "Catalogo polyglotto delle Plante," by the Contessa Aima de San Giorgio; but in none of these are the notices of English names quite satisfactory, though the last-named authoress was an Englishwoman, "*nata* Harley d'Oxford." With these we may join Seeman's "Popular Nomenclature of the American Flora," because, though confined to the American flora, it was intended as an introduction to the popular names of plants of the whole world—a large design which, unfortunately, was not carried further.

A strong effort has been lately made to popularise plants, especially exotic plants, by abolishing the Latin names and inventing new English names. On this vexed question I wish to say very little, except that I entirely dislike it, and am glad to see that the effort has been successful only to a very small extent. But there is nothing new in the effort. All the old writers, Gerard, Turner, Parkinson, Coles, Miller, and others, always gave English names with the Latin names, but for the most part the names given were only translations, and did not pretend to be more. It was the same with the great botanical works of the present century, as the *Botonical Magazine*, the *Botanical Register*, and the works of Sweet, Andrews, Lindley, and others, but in 1871 the *Botanical Magazine* gave up the practice. In the "Handbook to the British Flora" Mr. Bentham went a step further, and, largely dropping the old common names, he made an attempt to keep the Latin names in an English dress, but it did not become popular; and that is not surprising when we find among the suggestions such names as Common lapsame (*Lapsana communis*), six-stamened elatine (*Elatine hexandra*), procumbent helioscad (*Helioscadium nodiflorum*), maiden-hair adiant (*Adiantum capillus veneris*), sea peucedane (*Peucedanum palustre*), &c. We need only turn to Miller's "Dictionary of English Names of Plants," noticed above, a book written specially to advocate the giving English names to all plants, and we see at once that names are not made more simple by that means; but that it ends in confusion worse confounded. Two instances will suffice. For the English names of calochortus we have "butterfly tulip, butterfly weed, mariposa lily, wild tulip of California"; and as the English names of Eucalyptus resinifera we have "Botany Bay kino tree, gray or red gum, hickory of New South Wales, leather jacket, red mahogany of New South Wales." I prefer the simple and well-known names calochortus and eucalyptus.

However, I leave this vexed question, because I know there are many who go much further, and who despise not only scientific names for plants, but all names, whether scientific or trivial; and I have known some who have travelled far and wide with a real love for all that is beautiful in Nature, but with no wish to know anything of the history of the countries in which they travel, and still less of their geology, flora, or fauna. Such people have an utter contempt for all names of plants; they often have a keen eye to the beauties of Nature and to all natural scenery, and they delight in the forms and colours of flowers, birds, and insects, but they go no further; all that they see are simply pretty, or it may be grand, pictures, but no more; and to them the primrose by the river's brim is not even a primrose—it is but a spot of bright yellow in a green setting. Such travellers are in no sense naturalists; and if, as they often do, they publish their travels, the book is of no practical use; whereas a little trouble in finding out even the common names, and still better the scientific names of the flowers, birds, and insects, would have enabled many readers to see something of the scenes, and to share in the pleasure which the author found in his walks. But they will not, or do not, take this trouble, and content themselves with prefacing the account of their travels with the excuse for the barrenness of their descriptions—"I make no pretence to any scientific knowledge of any part of natural history."

But for those who wish to take a really intelligent interest in their gardening this studies, I would say this—plant names, family names, river names, field names, bird, beast, and fish names have all been the study of many learned men; and in our day, when everything that connects us with the past is sought out and commented on, the study of names of all sorts holds a high place in the estimation of scholars. And it is well worth noting how the unlettered savage and the great scholars meet on common ground in their respect for names. Ths savage gives life to every great object he sees—mountains, rivers, and hills; and he shows that they are to him living objects by giving them names, and when once so named they become to him sacred, and in many cases objects of worship, but not before. Travellers have noticed this in many parts of the world. Dr. Nansen, in his "Eskimo Life," tells us that in Greenland a man's name is not an adjunct, but an absolute part of the man: The name is as large as the man, and remains with him after death, and during life the name has a great influence on the man." He traces the same among the Norwegians, Lapps, Indians, and others; and that this respect for names, simply as names, is not confined to half-civilised nations we may see if we only go to our Bibles, where the value and almost sacredness of names of every sort is very remarkable. The old herbalists, when writing about plant-names, were delighted to think that they were treading in the steps of King Solomon, who "spake of trees, from the cedar tree that is in Lebanon unto the hyssop that springeth out of the wall," and so must have known their names.

But, putting that aside, I say without any hesitation that those who take delight in plants and flowers will find a fresh and lasting delight if they will study the names of the plants and flowers which they love. The two things are closely bound up together, but they never so clash that the pleasure taken in the one pursuit will interfere with the pleasure of the other. And if any are inclined so to add to the pleasures of their garden, the object of my paper is to show them that they may easily find many helps in the study, some of little value, perhaps, but most of them useful and trustworthy.

A New Raspberry-Blackberry Hybrid, has been raised by Mr Burbank, says the *Rural New Yorker*, and has been named Phenomenal. It is described as of a crimson raspberry colour, as productive as could be desired, and the most delicious of berries for canning and drying. The fruit grows in clusters of from five to ten or more, the individual berries measuring three inches around one way and four the other, weighing one quarter of an ounce each. It is claimed that this remarkable plant is hardy.

A MOST WONDERFUL BUILDING up of the constitution takes place after Holloway's famous medicines have been used for a reasonable time. They are pre-eminent above all other remedies, more particularly for the cure of liver complaints and disorders of the stomach; [illegible], bricklayers, &c. would find the Ointment invaluable for curing wounds, cuts, sores, [illegible]. Men in all conditions of life find it of incalculable benefit, as it penetrates internally, and thus strikes at the root of the ailment. The Pills act like magic in curing low spirits, and they repel all attacks on the nerves through excitement, excessive heat, brain worry consequent on business troubles, &c. They purify the blood, and give a new lease of strength to the constitution.—[ADVT.]

NEW PLANTS, FLOWERS, AND VEGETABLES.

PHAIUS NORMAN.

THIS is a most beautiful and distinct phaius, a hybrid between P. Sanderianus and S. tuberculosus. The growth is vigorous and erect, and the spikes are tall, and carry big attractive flowers. The blooms are about five inches across, with spreading sepals and petals of a rosy metallic hue, veined with carmine. The large spreading lip has old-gold coloured side lobes and base, a bright reddish-brown area veined with yellow and red, a front lobe of deep rose speckled with deep red, and a long golden disk spotted with red. F.C.C., R.H.S., March 8th. Messrs. Charlesworth and Co., Heaton, Bradford.

PHAIUS NORMAN ROSEA.

This is scarcely so robust as the type, and differs in having clear rosy sepals and petals, more yellow in the throat of the lip, and a more reddish front lobe to the latter organ. F.C.C., R.H.S., March 8. Messrs. Charlesworth and Co., Bradford.

PHAIUS NORMAN AUREA.

This form is as robust as the type, but has yellowish sepals and petals, and a yellowish base to the lip. The latter organ is also somewhat lighter than in other forms, but none the less beautiful and effective. All these three phaius are the result of seed produced in the same pod. A.M., R.H.S., March 8. Messrs. Charlesworth and Co.

LÆLIO-CATTLEYA WARNHAMENSIS.

A most brilliant hybrid with flowers four to five inches across; the sepals are somewhat narrow and of a curious shade of colour, yellowish with an orange-scarlet suffusion. The petals are broader and of a curious carmine hue, overlaying an orange ground; lip long and frilled, rich carmine at the apex with a bright orange yellow throat. A.M., R.H.S., March 8. Mr. Duncan, gardener to C. J. Lucas, Esq., Warnham Court.

DENDROBIUM ASTRÆA SUPERBA.

A handsome dendrobe with creamy sepals, and petals all tipped with deep rosy-purple. The lip is broad and long, creamy white with large orange base and dark brown stripes; the front lobe is tipped with deep rosy-purple. A.M., R.H.S., March 8. Mr. N. C. Cookson, Oakwood, Wylam-on-Tyne.

ODONTOGLOSSUM WILCKEANUM PITTÆ.

A remarkably beautiful odontoglot, and as robust as beautiful. The spike carried seventeen large flowers, and these have a rich yellow ground colour, on which are large and small blotches of rich chocolate-red. The edges of the segments are all slightly toothed and waved. Lip large, yellow, blotched with chocolate red, and with a gold disk striped with red. F.C.C., R.H.S., March 8. Mr. H. T. Pitt, Stamford Hill.

DENDROBIUM AINSWORTHII WOODHATCH VAR.

This is a superb form of a well-known hybrid, and surpassing it in size and effectiveness. The large segments are of a creamy-white hue, and the central purple area of the lip is of a deeper shade than usual. A beautiful orchid that is bound to become popular. A.M., R.H.S., March 8. Mr. Salter, gardener to J. B. Haywood, Esq., Woodhatch Lodge, Reigate.

CATTLEYA MIRANDA.

This is a bold cattleya obtained by crossing C. guttata Prinzi and C. Trianæ. The growths are stout and elongated, each bearing at the apex a pair of large leathery leaves. The sepals and petals are of a bright-rose colour, splashed and dotted with bright violet purple; the latter are two and a half inches long by an inch and a half broad. The lip has pale-rose side-lobes that clasp the column the whole of their length, thus forming a tube; the apex consists of a rich purple lobe frilled with deep violet purple. A.M., R.H.S., March 8. Messrs. J. Veitch and Sons, Chelsea.

HIPPEASTRUMS.

Navala is a splendid round form and a large flower; colour, bright-orange with white featherings at the bases of the segments. A.M., R.H.S., March 8. Messrs. J. Veitch and Sons, Chelsea.

Princess Osra is a most beautiful hippeastrum, with deep and intense orange scarlet flowers having a white centre and a clear and pure white band down the centre of each segment; a fine round flower of great size and substance. A.M., R.H.S., March 8. Mr. A. Chapman, gardener to Captain Holford, Tetbury.

AZALEA GRANDIFLORA ALBA.

A first-rate large-flowered and single azalea, with bold white flowers that measure almost five inches across. There is a yellowish tinge at the base of the segments, but not sufficient to detract from the general beauty of the variety. A.M., R.H.S, March 8. The St. George's Nursery Company, Hanwell.

CUCUMBER EVERY DAY.

We described this useful cucumber in our issue of February 12, and refer to it now because, after further consideration, the Fruit and Vegetable Committee consider it worth a first-class certificate. The fruits are handsome, bright green, and glossy, and with little waste. F.C.C., R.H.S., March 8. Mr. Owen Thomas, gardener to H.M. the Queen, at Frogmore, Windsor.

AGAVE SHOTTI.

A distinct species from Arizona. The linear leaves proceed from an ovate base, are a foot long, and form a dense rosette; the edges break away into slender fibres. The inflorescence rises to a height of four to five feet, bearing towards the apex a large number of bright yellow flowers. A specimen that flowered at Kew last year, and is figured in the *Bot. Mag.* t. 7,567, was purchased at the sale of Mr. J. T. Peacock's collection in 1889.

QUILLAJA SAPONARIA.

This is a Chilian tree with oblong leaves about an inch and a half in length and greenish yellow flowers about two thirds of an inch across. The tree is remarkable for the hardness of its wood, but more so for the saponaceous character of its bark; the bark is largely imported for the preparation of detergent hair washes, and it has been used for the purpose of revivifying stale beer. A specimen flowered last year in the celebrated garden of Mr. T. Hanbury, La Mortola, Ventimiglia, and a spray is figured in the *Bot. Mag.* t. 7,568.

Asparagus Sprengeri, a species from Natal that has gained much favour in this country on account of its long graceful growth and ferny foliage, has become wonderfully popular in the United States, where the market growers cultivate it on a very large scale. As a plant for home decoration it has been found to accommodate itself to the dry atmosphere of the living-room in a manner that has far exceeded the most sanguine expectations.

SCOTTISH HORTICULTURAL ASSOCIATION, March 1.

THIS robust and thriving society, which attains its majority this month, and seems to be advancing in numbers and in usefulness by leaps and bounds, held a very successful meeting on the above date. The meeting was held in Dowell's Rooms, Edinburgh, under the presidency of Matthew Todd, Esq., the genial president. After the usual minutes were passed and new members admitted, Mr. Todd called on Mr. Ireland, of Broughty Ferry, to give his lecture on "Orchids." The lecture was profusely illustrated by some fifty lantern slides photographed by the grower and lecturer—Mr. Ireland, so that we had the grower, the artist, the naturalist, and botanist all in one, and consequently one of the most pleasant and profitable evenings arranged by this useful society for its rapidly increasing members. It was only in the present century, Mr. Ireland pointed out, that orchids had excited absorbing interest or commanded much attention. They were, until a comparatively few years since, grown merely by the wealthy few, but of late years the number of collectors in all parts of the world had greatly increased, and we hear of 10,000 or 20,000 orchids in different centres of wealth and population. Mr. Ireland proceeded to ask and answer the question of what was an orchid in a lucid and interesting manner, as well as the equally difficult one of the cross-breeding of orchids, which had had such valuable practical results, as carried out by nurserymen and amateurs on the principles of Darwin. He then proceeded with most interesting historical and cultural notes on some of the more popular and beautiful genera, species, and varieties, such as lady's slippers, cattleyas, cœlogynes, lælias, lycastes, odontoglossums, oncidiums, dendrobiums, and vandas. On the motion of Mr. Dunn, supported by the President, a hearty vote of thanks was awarded to Mr. Ireland for his most interesting and instructive lecture.—D. T. F.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

ONE of the largest atttendances of members during the present season assembled on Monday evening last in the Club Room, under the presidency of Mr. C. B. Stevens, to hear a paper on "The Cultivation of a Few Useful Flowering Plants for Stove and Warm Greenhouse," by Mr. Townsend, gardener to Sir William Farrer, Sandhurst. The large attendance fully testified to the esteem in which Mr. Townsend is held, and appreciation of the services rendered by him in adding to the interest of the society's meetings by continued exhibits of interesting flowering plants, &c. The lecturer, in introducing his subject, said that in taking up the subject for the evening, he would treat with those plants which, with proper treatment, are easily managed, and are for the most part inexpensive to buy, and are prettier than houses of chrysanthemums which are grown in far too large a quantity in most private gardens, to the detriment of many beautiful flowering plants. The following subjects were touched upon, and short but ample cultural instructions were given of each:—Achimenes, Begonia manicata, B. Ingrami, B. fuchsioides, B. insignis, B. corallina, Justicia speciosa, J. flavacoma, Heterocentrum roseum, Centradenia rosea, Centropogon Lucianus, Clerodendron splendens, C. Balfouri, Scutellaria mocciniana, S. pulcherra, Eranthemum pulchellum, Thrysacanthus rutilans, Dendrobium nobile, Anthurium Scherzerianum, Phaius grandifolius, Zygopetalum Mackeyi, Libonia floribunda, Habrothamnus Newelli, Streptosolon Jamesoni, Salvia Pitcheri, Diplacus hybridus splendens, Torenia Fournieri, Exacum affinis. A lengthy discussion took place, which drifted chiefly to the advantage or disadvantage of pruning Dendrobium nobile. A hearty vote of thanks was accorded Mr. Townsend for his unique and practical paper.

An interesting collection of cut blooms was exhibited by the lecturer, the most noticeable being Centradenia rosea, Clerodendron Balfouri, Phaius grandifolius, Zygopetalum Mackeyi, Habrothamnus Newelli, Streptosolon Jamesoni, and the various begonias named above. Mr. Bound, Bill Hill Gardens, showed some blooms of a good type of Dendrobium Finleyanum, and Odontoglossum Rossi major.

MARKETS.

Covent Garden.

OWING to the short supply and keen demand for good fruit, prices are high. Oranges are moderately cheap. Vegetables fairly plentiful, but prices are rising. Potato trade slightly better than of late. Cut flower trade good.

FRUIT.— English grapes, 2s. to 3s. per lb.; Almeria, 12s. to 20s. per barrel; American and Nova Scotian apples, 12s. to 28s. per barrel; bananas, 5s. to 10s. per bunch; pineapples, 2s. 6d. to 6s. 6d. each; lemons, 8s. to 15s. per case; French pears, 6s. to 8s. 6d. per crate; Valencia oranges, 8s. to 16s. per case; Jaffa, 8s. to 12s. per box.

FLOWERS.—Arums, 2s. to 3s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 6s. to 9s.; Lilium Harrisi, 2s. to 4s.; tea roses, 6d. to 1s.; pink roses, 4s. to 8s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 6d. to 1s. 3d.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 3s.; Roman hyacinth, 4s. to 6s.; daffodils 4s. to 6s; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; wallflowers, 4s. to 6s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 4d. to 6d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 9d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Canary tomatos, 10d. to 1s. 6d. per tray, 3s. 6d. to 4s. 6d. per case; celery, 6s. to 12s. per dozen bunches; seakale, 12s. to 18s. per dozen punnets; eschallots, 2s. to 2s. 6d.; mushrooms, 6s. to 8s. per 12 lb.; English onions, 5s. 6d. to 7s. per cwt.; Valencia, 6s. 6d. to 9s. per case; Brussels sprouts, 2s. to 3s.; spinach, 2s. to 2s. 6d. per bushel; savoys and cabbages, 3s. 6d. to 5s, 6d. beetroot, 2s. to 3s. per tally; Italian cauliflowers, 2s. 9d. to 4s. per basket; Cornish broccoli, 6s. to 8s. per crate; cucumbers, 4s. 6d. to 7s. 6d.; French lettuce, 9d. to 1s. 3d.; endive, 1s. 3d. to 1s. 9d. per dozen; rhubarb, 1s. to 1s. 6d. per dozen bundles; carrots, 2s. 6d to 3s. 6d.; green mint, 4s. to 5s. per dozen bunches; asparagus, 2s. to 8s. per bundle; new Canary potatos, 10s. to 15s.; Malta, 16s. to 18s. per cwt.

Borough Potato Market.

No quotable change in price is reported; supplies are large, and the demand is steady.

Dunbars, 110s. to 120s.; Hebrons, 85s. to 100s.; Snowdrops, 80s. to 90s.; Bruce Maincrop and Sutton's Regents, 80s. to 85s.; Reading Giants and Saxons, 80s. per ton; Belgians, 3s. to 3s. 6d.; Germans, 3s. 6d. per bag.

Examples Worthy of Imitation.—One of the most pleasing features of the great chrysanthemum show of the Scottish Horticultural Association is the annual sale of flowers, &c., for the Royal Gardeners' Orphan Fund, this realised £30 10s. The sale was, we believe, under the management of the president, Mr. Todd, with the Misses Todd. Mr. H. J. Jones, of Lewisham, also adopts the excellent plan of keeping a special collecting box for the orphans through the chrysanthemum season, which gathered last year £14 3s. 1d.—the two making a total of £44 13s. 1d.—in addition to the £50 of its profits given to the same fund by the Scottish association. It is to be hoped that many more societies will go and do likewise.—D. T. F.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates

Four-Stemmed Hyacinth Spike.—S. C., Crouch Hill: The specimen sent was a curious example of fasciation, the four spikes being so tightly pressed together at the base as to become joined. If all the force of the bulb had been concentrated in the first instance on one good spike the result would have been better. It would appear that as soon as the four spikes proved too much for the bulb it endeavoured to bind them; too late, however.

Fringed Primula.—R. T., Tunbridge Wells: The primula sent is a very pretty one, but the flowers are scarcely large enough for modern growers. The flowers, however, are beautifully frilled and fringed, while the colouring is most attractive. The foliage is also distinct. If the habit is good and flowers are freely produced in large trusses it would be worth while to increase the stock now that the variety is fixed. You might submit a specimen to some nurseryman or seedsman who makes a speciality of primulas, just to test its value.

Currant Bud Gall Mite on Filberts.—E. H., Hailsham: We have never seen filberts infested with the bud gall mite previously, although the birch is sometimes badly attacked. Whether the same species (*Phytoptus ribis*) attacks all three, or whether there are several species, has not yet been ascertained. Too often the commencement of bud gall mite attack passes unnoticed, and so the bushes are infested before one is aware of the fact. Now that black currants are being so badly attacked it becomes the duty of every grower to carefully watch his bushes and remove swelled buds directly they are noticed.

Properties of a Good Primrose and Polyanthus.—A good primrose should have large flowers borne on stout stalks, so as to bring it [illegible] the foliage. The bloom must be regular in outline, clear in colour, flattish, [illegible] with the tube well filled with anthers. The properties of a good primrose [illegible] not so exacting as with the case of auriculas and polyanthuses. In the latter there must be a stout peduncle not too tall, carrying a large and full truss of flowers [illegible] "pips." Each flower must be regular, flat, and of a bright colour; the [illegible] tube should be well filled with anthers. In the case of gold-laced [illegible] the lobes must be evenly edged with yellow, and the edging must cut through the brown, red, or black of the lobe, and meet the central golden area. The [illegible] should be full and rounded, instead of loose and flat; disbudding is [illegible] necessary to ensure a good truss of finely-developed flowers.

Fungus on Chrysanthemums.—T. W. B, Sheffield: Your young plants are suffering from an attack of the Chrysanthemum Leaf Rust (*Trichobasis* [*Uredo*] *Chrysanthemi*), a fungus not unlike the Carnation Rust in many respects, and one that has done a large amount of damage in recent years. Your best [illegible] will be to cut away and burn all affected foliage, and dip the plants in a solution of sulphide of potassium, using half an ounce of this to one gallon of water. [illegible] the attack is very light it may not be necessary to remove the foliage, but [illegible] gently rub the fungus spots while dipping the plants. Where the stock is [illegible] to be affected it is a good plan to dip the plants at frequent intervals in [illegible] sulphide of potassium mixture until all signs of the fungus have disappeared. Over propagation and a close and moist atmosphere have probably placed [illegible] young plants in a position to court attack.

Caterpillars Attacking Herbaceous Plants.—E. H., [illegible] The specimen sent belongs to the ravenous group of Surface Caterpillars, [illegible] member of the genus Agrotis, and closely allied to the Heart and Dart moth. The mild weather has persuaded it to leave its winter quarters and feed upon the more succulent of the herbaceous plants; later on, if not destroyed, the caterpillars [illegible] turn to brown chrysalids, and a month after that the moth will appear and [illegible] lay eggs from which another generation of caterpillars hatch in a fortnight. Feeding is generally done at night. The best means of ridding the border of these pests is to lightly fork the surface and pick out the caterpillars as they [illegible] turned up, as they seldom go lower than three inches after they have [illegible] feeding. Fresh gas lime will quickly kill the caterpillars, but cannot be used [illegible] there are growing plants, as it would kill them. If, after careful searching, [illegible] still troubled with the pests it will be well to consider the advisability of [illegible] the plants to another site next autumn, gas liming the old border a [illegible] months before any other crop is inserted.

Crickets in Vineries.—T. W. B., Sheffield: There are many means [illegible] which crickets may be prevented from over-running vineries or other plant [illegible] fruit houses, but in every case as much depends upon the persistence of [illegible] operator as the means employed. The great failing is that if the remedy [illegible] effect its purpose at once to consider it worthless. Mix an ounce of arsenic [illegible] half a pint of honey and place portions of the mixture on pieces of glass [illegible] earthenware; stand these about the house where the crickets are plentiful [illegible] evening, and remove them in the morning. On no account admit [illegible] domestic animals to the houses where such poisonous baits are [illegible] mixture should serve for three successive nights provided it is not all [illegible] that period it will become too dry to tempt crickets and cockroaches. [illegible] sized box with holes bored in sides and top, and filled with [illegible] oatmeal mixed with dry salt, will also prove an attractive trap. If the [illegible] the crickets frequent can be found, pour some carbolic acid into them. [illegible] keeping to the honey and arsenic it will be advisable to tempt the crickets [illegible] times with white powered arsenic mixed with roasted apple; this can be placed about the houses like the honey mixture. In all instances be very careful, for arsenic is a deadly poison. Rhubarb leaves are said to be palatable and poisonous to crickets; we have not tried them.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

J. T., Drighlington: Oncidium splendidum, a very good form.

S. F. C., Crouch Hill: 1, A species of Amomum, send when in flower; 2, Maranta bicolor.

S. M. C., Uppingham: One of the numerous florists' forms of the double Anemone coronaria. It is quite hardy, but can be grown in frames or greenhouse.

W. T., Hull: A double form of Narcissus pseudo-narcissus.

L. S. P., Stockport: 1, Chionodoxa Luciliæ; 2, Scilla præcox; 3, the common snowdrop, Galanthus nivalis.

S. A., Lincoln: 1, Dendrobium heterocarpum; 2, Odontoglossum cirrhosum.

Names of Fruits.—We are pleased to assist our readers as far as it is possible to do so in naming fruits, but it is absolutely necessary that they should send us good specimens carefully packed, as it is only when characteristic examples reach us in perfect condition that we are able to determine their names. We are compelled to insist on the observance of this rule, as so many specimens now reach us. We cannot undertake to name more than six varieties at one time; and both apples and pears should be sent when approaching maturity, but before they are fully ripe, that we may have the assistance of their distinctive colours in determining their identity.

G. V., Wotton: The apple is Bess Pool.

H. G., Isle of Wight: The variety is apparently not known, and is probably a local one. If you have a good dish of fruits left send some along to the next R H.S. meeting, together with a letter stating what you know of the variety. Give the variety a name and enter it to come under the notice of the Fruit Committee. Ryde Beauty, Island Queen, or some such name would be appropriate, and give some idea of the origin of the variety.

Communications Received.—J. T.—S. F. C.—S. M. C.—W. T.—L. S. P.—S. A.—G. V.—H. G.—R. T.—S. C.—E. H.—G. R.—G. H. H.—W. M.—W. G.—S. C.—R. L. H.—W. L.—B.—A. S.—W. G.—D. R. W.—J. C. T.—G. S.—D. T. F.—H. C. P.—J. L. and S.—W. C.—A. C. R.—R. W.

N.C.S. ACCOUNTS.

THERE are several items in the recent statistics that need further explanation. Take, for instance, the two that bulk out so heavily in show expenses—cartage and the hire of plants As for the first, most exhibitors elsewhere pay their own, and have not seldom found that the cost has equalled or exceeded the prizes. But the hire of plants for a great National society's show seems quite unique, and, so far as my knowledge extends, altogether unknown in the provinces. It cannot be that exhibitors are paid for the hire of their plants, else they might be paid twice for the same material—once in prizes and again in hire. We have seen and read a good deal of the evils of overcrowding at chrysanthemum and other shows, but until your issue of March 5 never remember to have read of such sums as £18 15s. 9d., £61 5s., £19 7s. 6d., £17 6s., &c., being paid for the hire of plants as in the case of the shows of the National Chrysanthemum Society. Surely, with the cream of chrysanthemum growers among its members as exhibitors, there should be no space for hired plants at its great shows. Such practices may admit of explanation and justification, but meanwhile not a few distinguished growers fail to see how this hiring of plants contributes to the proficiency of exhibitors, or to the adornment and ennoblement of the science and practice of horticulture.

D. T. F.

OBITUARY.

MR. RIVERS H. LANGTON, we greatly regret to announce, died a few days since at his residence at Hendon, after a brief illness, at the age of thirty-six. Mr. Langton, who succumbed to pneumonia, following on influenza, was an ardent lover and successful exhibitor of the rose, and was a highly-respected and active member of the committee of the National Rose Society. At the meeting of the committee of this society on Tuesday last, much regret was expressed that the society should have lost so valuable a member, and a vote of condolence with the members of his family was unanimously passed. His cheery, helpful presence at the exhibitions and meetings he was in the habit of attending will be sorely missed by his many friends. It is proposed to show the estimation in which Mr. Langton was held by presenting to the National Rose Society a memorial cup, to be competed for by amateurs.

THE BARDNEY SEED FIRM.

SOME nine miles from Lincoln is the town of Bardney. It is the centre of a typical agricultural district. The land is, almost without exception, devoted to farming and market gardening, and this part of Lincoln is noted for its extensive seed farms, which is small matter for wonder, considering the fine system of drainage and irrigation, by which many a square mile of land has been converted into an area that is naturally productive.

On entering Bardney the first object that attracts the attention of the visitor is a modern building of large proportions, with a vast amount of storage area, and with up-to-date accommodation and conveniences for the reception of produce, and light and well-ventilated offices included in the construction. If there is one feature that constitutes the local lion, surely here it is; and the proprietor of the concern, Mr. William Sharpe, is as courteous as his business is prominent. The Bardney seed firm of Messrs. John Sharpe and Son was founded by Mr. John Sharpe, and by him carried on with increasing success until he was eventually joined in the conduct of the business by his son, and on his becoming a member of the firm the prosperity became so marked that, upon his assuming a felicitous domestic responsibility, the auspicious occasion was marked by the passing of the entire commercial control into his hands. Mr. John Sharpe still resides at Bardney, and, although enjoying a well-earned rest, he still takes an active interest in matters pertaining to horticulture, as witness the private gardens attached to his residence, and the range of vineries that adjoin it, which, in season, are of much interest. The gardens are in the charge of Mr. W. Rowland, a trusted servant of many years' appointment, whose pride it is to show to visitors his various stocks and stores.

Of the evolution of the seed business, which forms the chief consideration of the present article, is may be said that, at the present time, Messrs. Sharpe's seed specialities are grown in the Royal Gardens; that large consignments are dispatched in every direction to British and foreign orders; that Governmental contracts for cereals, cultivated for consumption in prison and convict establishments, and, therefore, owing to the simplicity of the dietary, subject to exacting experimental scrutiny; and last, although by no means least, that the productiveness of the seeds sent out is claimed to be of a very high percentage. These are sufficient proofs, were they wanted, that the gradual but substantial development of the business is assured, since it is apparently progressing upon right lines. As in the case of all leading seed growers, there are extensive trial grounds, which are situate round about Bardney; so that, in the case of their own novelties and of other leading varieties originally obtained elsewhere, the stock is very carefully tested, and grown under close personal supervision with the additional advantages to constitution and habit obtainable from cultivation in this favourable district. To meet the requirements of the times, new things are called into being, and the list of introductions brought before the horticultural public during recent years would probably form no inconsiderable list.

Especially is the kitchen garden laid under tribute. In 1895 appeared the Early Eight Weeks' pea of medium height, healthy growth, and asserted to be the earliest known variety. A later introduction that has been put upon the market this season, in fact, is King of the Earlies, which ought to rank royally amongst the table delights of the season, since it has a generous flavour and culinary excellence. It is also of very fair growth, and its podding capacity is ample; considerations that should win for it universal appreciation. A very fine tall-growing pea is the Duchess of York, a marked improvement among second early varieties, and it has been described by one who has a reputation at stake, as the best wrinkled pea he has ever seen; a good bearer and of exquisite flavour. To the cultivation and production of beans much attention has been given with unusually good results. The Elephant Long Pod is one of the latest; it is of remarkable length, and a photo submitted illustrates a well-formed bean of good size, and abundant in seed. It is dwarf of habit, very early in ripening, and promising well for exhibition, if only ordinary care be bestowed upon it. Another variety, Lincolnshire Mammoth, is also claimed to be an acquisition to the table, and a pronounced success for show purposes. Much attention is also given to the cultivation of potatos, the most noteworthy varieties introduced by this firm being: Lucania, an early white kidney of excellent quality and a splendid exhibition variety; Early Six Weeks, said to be the earliest round yet sent out, and although a coloured variety, has proved most valuable on light land; Campania is of this year's introduction, and is likely to prove one of the most valuable varieties sent out for many years; it is a heavy cropper, and ready to lift at the same time as Victor; Mainstay is an oval-shaped variety, quite free from disease, a prodigious cropper, and met with much success on the exhibition table during the past season. At the Liverpool root show, held on October 9 last, Mainstay won the first prize as the best late variety, also a special prize for the best dish or dishes of potatos, and a special prize for the best dish of potatos any other shape except kidney or round. These are but a few items selected from an exhaustive list of good things, equally suitable for the kitchen garden.

Ample provision is made in flower seeds, this section of the business receiving much thought and care. The nurseries devoted to their culture are under skilful and adequate management, while no expense is spared to secure the best results. The cineraria is a favourite here, as, indeed, everywhere. Bardney Beauty is noted for its fine blooms and distinct colours. The sustained popularity of the aster for all purposes has led to the inclusion of many beautiful varieties of this justly popular flower. An exceedingly graceful sort, Improved Giant Comet, has

HEATING APPARATUS.

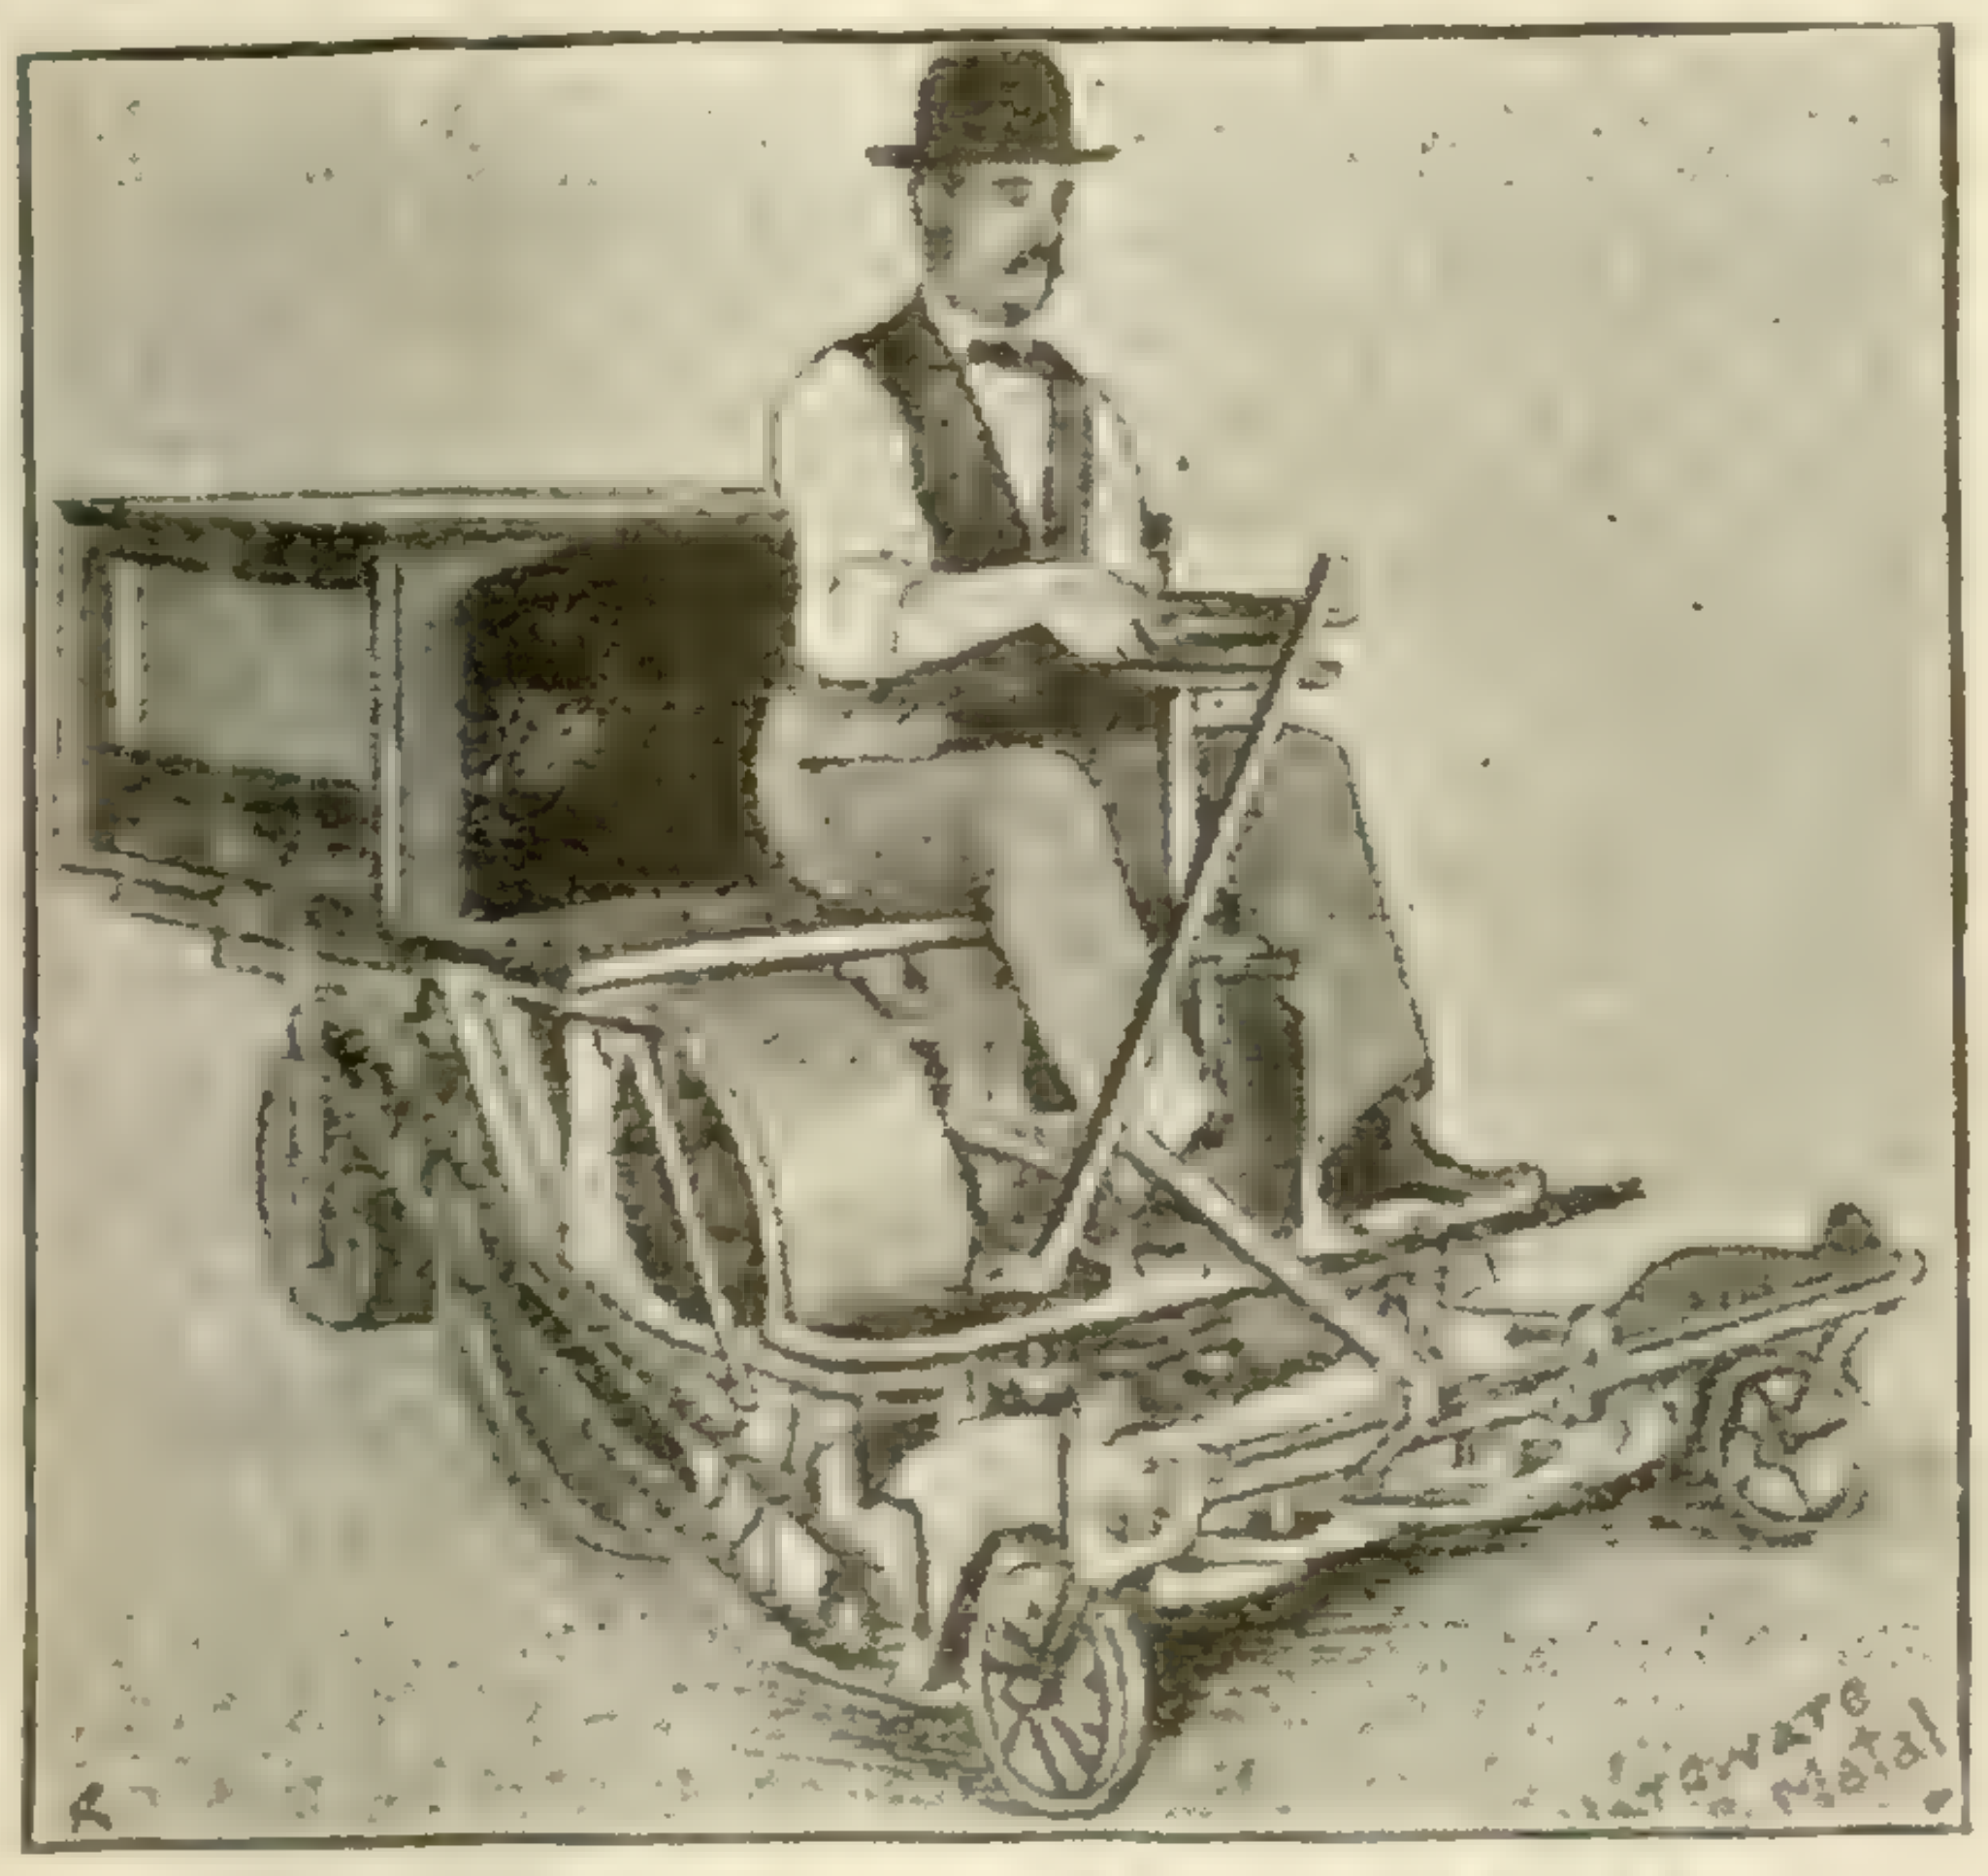
Works and Head Offices: STOURBRIDGE. London Branch: 35, Old Queen St., WESTMINSTER, S.W.

a profusion of graceful ribband-like petals of varied hues; it is a large and very free bloomer, lasts long in perfection, and is equally adaptable for pot purposes or for out of doors. New Barcney is another charming variety, being more compact of form than the preceding, but exceedingly free, and of special value for garden embellishment. Border flowers include many promising specialities, particularly of the kinds more commonly in request. In this group are many choice strains deserving a trial. For growth under glass there are superb Double-fringed Petunia, Perfection Giant Primula, and Selected Giant Gloxinia, all good things to be included in the seed list.

Messrs. John Sharpe and Son have achieved a worthy record, and it is not too much to expect that under the superintendence of the present chief, and with corresponding continued enterprise, its future prosperity is secure.

NEW INVENTIONS.

The Motor Lawn Mower.—We have had the Steam Lawn Mower with us for some time, and now comes the Motor Lawn Mower from America. This machine is driven by a four-horse power gasoline engine, and the weight is distributed over three sets of rollers. Where large areas have to be regularly mown this should prove a desirable and economical machine, for it cuts and rolls the sward and there are no horse-hoof marks left behind. The cutting frame is directly connected with the engine shaft by sprocket and chain, and by means of a lever the operator can lift the cutting frame from the ground and fold it back against the main body of the machine. There are provisions for reversing the motion and throwing the more delicate parts out of gear if necessary. The direction and speed of the mower are completely under the control of the driver by means of the two wheels placed conveniently in front of his seat on the engine frame platform.



GASOLINE MOTOR LAWN MOWER.

The mean reading of the Barometer during the week at Greenwich was 29·65 inches, and that of the Thermometer 38°·9, the latter being 1°·5 below the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 11 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 15·1 hours. The measured rainfall amounted to 0·59 of an inch.

ENGAGEMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 14.—United Horticultural Benefit and Provident Society; Annual Meeting at Caledonian Hotel, Adelphi; chair to be taken at 8 p.m. by Mr. George Wythes.
TUESDAY, MARCH 15.—Annual Dinner of the London Fruit and Potato Trades Benevolent Society.
THURSDAY, MARCH 17.—Meeting of the Linnean Society.

AUCTIONS.

MONDAY, MARCH 14.—Iris Germanica, Lilies, Carnations, Begonias, Dahlias, Roses, &c., at Protheroe and Morris's Rooms.
TUESDAY, MARCH 15.—Carnations, Gladioli, Roses, Montbretias, Cannas, &c., at Protheroe and Morris's Rooms.
WEDNESDAY, MARCH 16.—Liliums, Carnations, Vallotas, &c., at Protheroe and Morris's Rooms.
WEDNESDAY, MARCH 16.—Palms and Plants from Ghent, Roses, Fruit Trees, Border Plants, &c., at J. C. Stevens's Rooms.
THURSDAY, MARCH 17.—Plants, Shrubs, Lilies, Bulbs, Roses, &c., at J. C. Stevens's Rooms.

Lists and samples free.—A. POTTER, Melbourne Netting Works, Wolverhampton. Maker to the Queen and Prince of Wales.

THE WEST'S
PATENT
IVORINE PLANT
LABELS.

The "Ivorine" Writing Disc being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon by a common lead pencil or pen and ink, it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, and does not become unreadable, as is the case with all painted labels as the paint gets old. The copper wire shank may be used as per the illustration, or it may be bent round the stem of a plant, leaving the name showing in the most readable position.

Samples and Lists of the West's Patent Specialities post free.

8s. per gross, Carriage Paid.

Supplied by all Nurserymen, Florists, &c.

SUMMER CLOUD.
ELLIOTT'S New Shading for Glass Houses.

TRADE MARK—NO. 14,629.
Sold in Packets, 1/- each, and in Bags, 7 lbs., 10/6 ; 14 lbs., 20/-

IT combines efficiency with appearance, convenience with economy, and its effects are lasting. It is easily removed when necessary with hot water. It can be supplied either pale green or grey.

Beware of spurious imitations, which are offered through the success obtained for many years by Elliott's "Summer Cloud" Shading, and see that in ordering you get the "Summer Cloud," which is the only original and bona fide article, with the Trade Mark on each packet.

To be had of Seedsmen and Florists. Manufacturers—

CORRY AND CO., LTD, FINSBURY STREET, LONDON.

The Beauty of an English Garden is a

GOOD LAWN

Yet how often one sees poor yellow, moss-grown spaces in place of green, velvety turf. The cause is poverty, constant mowing, and nothing done in the way of restoring the exhausted fertility. Stable manure is an eyesore on a neat Lawn, but

PEARSON'S CHEMICAL MANURE

may be applied with little trouble or expense, and is washed in by the first shower. Will not burn the grass as some compounds do. Apply 2 oz. to square yard any time from now to end of March, 14 lbs., 4s. ; 28 lbs., 7s., in Tins. ½ cwt., 12s. ; 1 cwt, 20s.

TESTIMONIALS FREE.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

IMPORTANT AUCTION SALE.

MR. WILLIAM BULL, having disposed of the Ground of his Branch Nursery in the Ashburnham Road, Chelsea, for Building, the land must be cleared by Midsummer. The whole of the contents, therefore, of Twenty Houses, including—

THOUSANDS OF CHOICE ORCHIDS,

WILL BE SOLD BY AUCTION, ON THE PREMISES, BY

MESSRS. PROTHEROE & MORRIS,

OF CHEAPSIDE,

WITHOUT THE LEAST RESERVE.

ON MONDAY, MARCH 28, 1898,

And THREE FOLLOWING DAYS.

A CATALOGUE of the ORCHIDS is now ready, and can be had of the AUCTIONEERS, or of Mr. WILLIAM BULL, 536, King's Road, Chelsea, S.W.

The above will be followed the LAST WEEK IN APRIL, by a SALE WITHOUT RESERVE, of

THOUSANDS of CHOICE STOVE, GREENHOUSE, and HARDY PLANTS,

SPECIMEN PALMS, AND OTHER ORNAMENTAL PLANTS,

SUITABLE FOR LARGE CONSERVATORIES, WINTER GARDENS, &c.

The Houses, Boilers, and Hot-water Pipes will be Sold on the Last Day of the Sale in April.

CATALOGUE NOW IN PREPARATION, and will be READY SHORTLY.

As all the Houses and Ground must be cleared, this Sale, being Without Reserve, presents an unique opportunity of acquiring Orchids, New and Rare Plants, and Specimens for Greenhouse and Conservatory Decoration.

Business will be carried on at MR. WILLIAM BULL'S ORIGINAL ESTABLISHMENT FOR NEW AND RARE PLANTS, 536, KING'S ROAD, CHELSEA, LONDON, S.W., as usual.

COMPETITION DEFIED!

OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

☛ **ALL FLOWER SEEDS CARRIAGE FREE.**

1898 FORBES' CATALOGUE 1898
(over 150 pages—nearly 150 illustrations) of

FLORIST'S FLOWERS and HARDY BORDER PLANTS
is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.

It gives full and ACCURATE DESCRIPTIONS of everything in the way of FLORIST'S FLOWERS, also COLOUR, HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.

It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

SHEPPERSON'S NOVELTIES & SPECIALITIES.

—— THIRTY-NINTH YEAR OF ADVERTISING. ——

The following NOVELTIES and SPECIALITIES having all been grown in a very exposed situation high up on the Derbyshire hills are very hardy, stocky, and healthy, very different to weak seedlings grown in warm favoured situations, which look nice, but very rarely succeed well. All Carriage Free for Cash with order. Descriptive List free.

CHRYSANTHEMUMS (Special Culture), not a collection of old-fashioned sorts, but the cream only of the best English, French, American, and Japanese raisers. Good, well-rooted plants, 12 for 2s., 25 for 3s. 6d., true to name.

CARNATIONS, PICOTEES, and CLOVES of the finest-named hardy border varieties, many grand new sorts, strong layers wintered outside, 6 for 2s. 6d., 12 for 4s., 25 (in twelve varieties) for 7s. 6d., unnamed varieties 3s. per doz.

NEW HARDY JAPANESE PRIMULAS.—This class of hardy Primula, which has become so popular either for the outside border or the greenhouse since its introduction, has been greatly improved. Six distinct varieties (named) for 2s. 6d.; 12 for 4s.; 25 in 12 varieties for 7s. 6d.

CARNATIONS, PICOTEES, and CLOVES.—Will produce 80 per cent. of fine double flowers, in self, striped, and spotted varieties, including whites and yellows, all from the finest strains for the borders. 12 for 2s. 6d., 25 for 4s. 6d., 50 for 8s.

PRIMULA CASHMERANA.—A really fine spring-flowering plant. Colour, bright mauvy violet. Free bloomer Should be in every garden. Three for 1s. 6d., 6 for 2s. 6d., 12 for 4s.

PHLOXES (Perennials).—Special culture of early and late varieties, the cream only from Downie, Laird and Sons, Kelway, Ware, and other first growers. Six fine varieties for 2s., 12 for 3s., 25 for 5s. 6d., true to name. Strong stools to bloom well.

VIOLAS, during the past few years, have come to the front as few flowers have ever done. They are wanted everywhere, and very few plants produce so fine a display for so little trouble. I have a grand collection, including many new varieties. 12 varieties, 1s. 6d.; 25 for 2s. 6d.; 50, in 25 varieties, for 4s. 6d.; true to name.

PYRETHRUMS (Double and Single).—A grand collection to name, selected from the best English and French raisers as a hardy, free-flowering, easily-grown plant for all purposes. 3 named varieties, 1s. 6d.; 6 for 2s. 6d.; 12 for 4s.; unnamed varieties, 3s. per dozen.

GAILLARDIAS (Perennial Hybrids). — A really grand collection of these most gorgeously marked hardy plants. Colours—Scarlet, crimson, and gold, of different shades; blooms all summer; good strong plants, 6 for 1s. 6d.; 12 for 2s. 6d.; 25 for 4s. 6d.

HOLLYHOCKS. — Warranted all fine double flowers; Chater's and Ware's select strain, strong year-old plants to bloom this summer. 6 varieties, 2s.; 12 for 3s.; 25 for 5s. 6d.

ASTERS (Michaelmas Daisies).—Unrivalled hardy autumn-flowering border plants, for cut flowers, &c. A grand collection of the latest improved colours. Six distinct sorts, 1s. 6d.; 12 for 2s. 6d.; 25, in 12 varieties, 4s. 6d.

CANTERBURY BELLS. — Grand new colours and new forms, double and single, Hose in Hose, Cup and Saucer, and other varieties, 12 plants to bloom well, 1s. 6d.; 25 for 2s. 6d.

GERANIUMS. — Greenhouse varieties. Double and single, by Pearson, and other first-class raisers. Good, well-rooted plants, out of pots, 3s. per dozen; true to name.

DELPHINIUMS. — A splendid lot, raised from 12 varieties of Kelway's. Double and Single, including all shades of Blue, from the very palest to the darkest. Good plants to bloom well, 6 for 2s.; 12 for 3s.; 25 for 5s. 6d.

IRIS GERMANICA.—Rivals of the famed orchid, flowers of peculiar formation, and most exquisitely marked with many bright and distinct colours. Quite hardy. 3 named varieties, 1s. 6d.; 6 for 2s. 6d.; 12 for 4s.; 25, in 12 varieties, for 7s. 6d.

GEUMS.—The new Double Scarlet. A splendid hardy, free blooming plant, fine for cutting, 12 for 1s. 6d.; 25 for 2s. 6d.; 50 for 4s. 6d.

AQUILEGIAS.—A grand collection, including many new colours and new forms; 12 best mixed varieties for 2s.

PENTSTEMONS.—A splendid collection to name; a very showy and useful bedding plant, 3s. per dozen; 25 for 5s. 6d.

PINK (Fimbriata alba major) —Large white fimbriated flowers. A very free bloomer. Should be in every garden. Good plants 2s. per doz.; 6 for 1s. 3d.

CAMPANULA PERSICIFOLIA. — Single White, Double White, Single Blue, and Double Blue. All quite hardy, and unrivalled for border decoration, cut flowers, wreaths, &c. 1 of each for 1s. 6d.; 2 of each for 2s. 6d.

DORONICUMS (Golden Stars or hardy Marguerites).—Three first-class sorts. Harper Crewe, Clusii, and Plantagineum excelsum. 1 of each for 1s. 6d.; 2 of each for 2s. 6d.

TOMATO PLANTS.—Two first-class varieties, Challenger and Conference; good plants, 1s. 6d. per doz. Ready in April; order at once.

12 BEAUTIFULLY Spotted or pure White FOXGLOVES for 1s. 6d.; 25 for 2s. 6d.

POLYANTHUS and PRIMROSE (Hybrids).—Splendid mixed colours; finest strain grown. 12 for 1s. 6d.; 25 for 2s. 6d.; 50 for 4s. 6d.

ARMERIA (Thrift). — Pink and white flowers. Plant dwarf and cushion-like. Very useful for rockeries and edging to borders. Quite hardy. 2s. per dozen; 25 for 3s. 6d.

LYCHNIS DIOICA RUBRA.—Double crimson flowers. A useful, neat plant. This has been greatly admired by all who have seen it; three for 1s. 6d.; six for 2s. 6d.

12 HARDY Perennial BORDER PLANTS, named, distinct, and useful for decoration and cutting purposes, 2s.

POTENTILLAS.—A distinct and interesting class of hardy border or rock plants, producing an abundance of flowers of a splendid velvety texture, which are very attractive and ornamental, and for cut flowers they are grand. Three for 1s. 6d., 6 for 2s. 6d., 12 for 4s., true to name.

FUCHSIAS, for Exhibition or Decoration. Order at once for delivery in April. I have a very fine collection, including many new varieties, double and single, light and dark, good healthy plants, 2s. per dozen, true to name.

A MAMMOTH SWEET WILLIAM (Holborn Glory).—This is, without doubt, the largest-flowered Sweet William ever sent out, the florets being much larger than penny pieces. An unequalled speciality for collections of biennials, border, or herbaceous plants. Unaproached for show, exhibition, or staging purposes. 12 for 1s. 6d., 25 for 2s. 6d., good strong plants.

CARNATION.—Margaret. This grand novelty has proved itself to be the most remarkable of all the carnation family. It commences to bloom early in summer and go on till late autumn. It will produce quite 80 per cent. of fine double flowers of a great variety of the most beautiful colours and markings. 12 plants for 2s., 25 for 3s. 6d.

SEEDLING PANSIES (Fancy). — Strong plants to bloom well. 1s. 6d. per dozen, 50 for 5s. 6d.

STRAWBERRY PLANTS.—British Queen, Brown's Wonder, Duke of Edinburgh, President, Sir Joseph Paxton, Sensation, and many other good sorts, strong fruiting crowns. 3s. per 100.

WALLFLOWERS.—Ware's Dwarf Blood-Red and Yellow, also Primrose Dame, good strong plants, all transplanted. 1s. per doz., 6s. per 100.

SAMUEL SHEPPERSON, Florist and Seedsman, Prospect House, Belper, DERBYSHIRE.

Williams'

SHADING MATERIALS.

THE MOST SUITABLE FOR

SHADING ORCHIDS, FERNS,

Palms, and Stove and

GREENHOUSE PLANTS

WILLIAMS' HOTHOUSE SHADING.

It is a strong, durable Cotton Netting, woven in squares so close as to exclude the direct rays of the sun, but admitting the greatest amount of light attainable through shading.

It withstands the weather better than any other class of Shading, and may be beneficially used on account of the thickness of its texture, during cold weather, to keep the frost out. The leading Orchid and Plant Growers in the country have used this material for some years; and speak very highly of it, pronouncing it to be the very best material for Plants they have ever used.

Blinds made up and fixed complete.

Sold in pieces 30 yards long by 1⅓ yards wide.

Price **40s.** each. Samples submitted gratis.

WILLIAMS' "EUREKA" SHADING. *Regd.*

This new shading is in the form of a white powder, and is prepared for use by applying boiling water to the compound, and allowing it to cool, when it can be applied by means of a brush. It dries instantaneously, and can be rubbed off easily when moist. This shading may be used for GREENHOUSES, SKYLIGHTS, WINDOWS, &c.

Sold in 1 lb. packets, with directions for use, price **1s.** each.

1 lb. free by parcel post for 1s. 3d.

2 lb. free by parcel post for 2s. 4d.

Each packet will make half a gallon of shading material when mixed. It is a great improvement on anything hitherto offered, and lasts the whole season.

B. S. WILLIAMS & SON,
Victoria and Paradise Nurseries,
Upper Holloway, London, N.

"EUREKA" WEED KILLER,

THE GARDENER'S FRIEND.

SATURDAY, MARCH 19, 1898.

ASCOT, SUNNINGHILL, SUNNINGDALE, AND DISTRICT HORTICULTURAL SOCIETY.
CHRYSANTHEMUM SHOW.
Observe the correct date is NOVEMBER 2 and 3, not as recently advertised, 16 and 17.
The Glen, Ascot. HENRY C. NEEDHAM, Hon. Sec.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.
GRAND SPRING SHOW.
MARCH 29 and 30.
For Schedules apply SECRETARY, 37, Preston Road.

ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER AND THE NORTHERN COUNTIES.
£600 IN PRIZES.
Schedules of the Manchester Flower Shows are now ready, and may be had free on application to
P. WEATHERS,
Curator and Secretary,
Royal Botanical Gardens, Manchester.

SHREWSBURY GREAT FLORAL FETE,
AUGUST 17 and 18, 1898.
The Prizes in the Schedule amount to £950, with Gold and Silver Medals, &c.
Schedules post free on application to the Hon. Secs.,
Messrs ADNITT. and NAUNTON, The Square, Shrewsbury.

WALTON AND WEYBRIDGE CHRYSANTHEMUM SOCIETY'S TWENTY-FOURTH ANNUAL SHOW, THURSDAY, NOVEMBER 10. Open Class, 48 Blooms, ten-guinea cup, and £3 3s. For schedules apply
GEO. MASTERS, Florist, Walton Road, East Molesey, Surrey.

WOLVERHAMPTON FLORAL FETE.—THE TENTH ANNUAL HORTICULTURAL SHOW AND FETE.
will be held JULY 12, 13, and 14, 1898.
Prize Schedules and Entry Forms from—
WILLIAM E. BARNETT, Secretary, Snow Hill, Wolverhampton.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at One Shilling per line, the minimum charge being Five Shillings. Advertisement Office, 148 and 149, Aldersgate Street, London, E.C.

NOTICE TO ADVERTISERS.

Owing to the continued increase in circulation, the "Gardeners' Magazine" will in future go to press earlier. No advertisement can be guaranteed insertion, or altered, unless received before Four p.m. on Wednesdays.

NOTES OF THE WEEK.

COST OF PUBLIC PARKS.

FOR some time past there has been a brisk discussion in a section of the dailies of the question of the cost of management of the public parks under the control of the London County Council. It has been readily acknowledged that the parks have been maintained in such excellent condition as to justify a feeling of pride on the part of the residents in London; but the opinion has been freely expressed that the annual expenditure has so grown as to border on extravagance. In the case of Battersea and Victoria Parks, which are unquestionably the two most important open spaces of which the London County Council has charge, it is pointed out that the cost has increased by some 40 or 50 per cent. since they were handed over by the Government to the Metropolitan Board of Works, which has been superseded by the Council. The cost of Battersea Park immediately preceding the transfer in 1887 was £8,910, as compared with £12,775 in 1897-98; and the estimate for Victoria Park last year was £11,855, against £8,316 in the year previous to the park coming under the control of the Council. These increases are unquestionably substantial, and justify some inquiry on the part of those responsible for the expenditure of the ratepayers' money; but they do not necessarily prove that there has been some degree of extravagance as assumed by some of those who have taken part in the discussion. Before the expenditure can be properly regarded as extravagant, it must be satisfactorily determined that either full value has not been obtained from the outlay, or that the maintenance has been carried to a point beyond the requirements of the respective districts. In the case of the two parks here referred to, as of other of the open spaces under the control of the Council, there has evidently been an earnest endeavour on the part of those responsible for their management to render them attractive and convenient, but there have been no signs of a desire to go beyond these two points. It should be remembered in discussing the cost of the public parks that the conditions which have an important bearing upon the expenses are not exactly the same at the present time as they were ten or twelve years ago. During this period there has been an enormous development in the taste for outdoor sports during the period, and the continuous use of every foot of available space for cricket in summer and football in winter, necessitates a heavy additional annual outlay in the maintenance of the turf in good condition. There must also have been a material increase in the cost of maintaining the buildings in repair. As both these parks are comparatively recent creations, the glass structures could not, during the time they were under the charge of Her Majesty's Office of Works, have required much beyond an occasional coat of paint, but of late years they have probably needed more substantial repairs. In both parks there has been an increase in the area under glass, more especially for the purpose of the chrysanthemum exhibitions which, by reason of their extent and beauty, afford unbounded pleasure to immense numbers of the poorer classes resident in London, who, but for the annual displays provided in the public parks, would have no opportunity of seeing the chrysanthemum in its full glory. Again, the additions that have been made to the wages of the labourers during the past ten years, must contribute materially to the total increase in the expenditure; but in no case have they been greater than was necessary, and, to state the case generally, the cost of the parks is in no way excessive, having regard to their extent and the admirable condition in which they are maintained.

EARLY TULIPS.

A WALK through our gardens reveals, to anyone at all observant, the fact that the early tulips so extensively used with such excellent effect as bedding arrangements are thrusting themselves through the soil, obedient to the law of their being which fixes spring as the season of their floral service. The early tulip is a subject of great value to the gardener, supplying him with delicate and brilliant blossoms when flowers are naturally scarce, because it lends itself to rapid forcing. The pretty Van Thol varieties led the way, as they are first in the order of blooming, and though dwarf in height and comparatively small in flower, they possess the fragrance of their progenitor, the South European Tulipa suaveolens. This race, the individuals forming it being somewhat limited in number, are of value in filling baskets and jardinieres for indoor decoration, and they are imported in considerable numbers for the purpose. The scarlet Van Thol is such an advance in size over the white, yellow, rose, and other varieties, that it can be readily imagined it came of more mixed parentage; it is also well adapted for and forms a charming bed in the open, while the others are more adapted for pot culture. T. pubescens, which is regarded as a probable hybrid between T. Gesneriana and T. suaveolens, is considered to be the progenitor of a race of rather later flowering early tulips, of which the Pottebakkers, Bride of Haarlem, Couleur Cardinal, and a few double varieties, are the representatives. In all probability the actual parentage of our most popular varieties will never be finally determined, for one has only to contrast the giant and massive forms of Keizer's Kroon and Proserpine, their tall growth and erect stature, with smaller and dwarfer forms that yet flower at the same time, to come to the conclusion that the former are the offspring of mixed parents. We have, perhaps, no early tulip that can compare with Keizer's Kroon for size and beauty, and yet it is more than half a-century old, and when it first bloomed it must have been regarded as a veritable floral phenomenon; and in the case of this particular variety we have a remarkable illustration of heredity in flowers, for the flowering bulb of a tulip perishes when it has finished its season's task, whether or not it has flowered, but perpetuates its variety in the offsets formed on the radical plate of the parent, and they transmit with unvarying regularity the exact characteristics of the individual from which they were derived, though a little sportiveness is sometimes noticed, such as a partial attempt on the part of a self to break away into some ill-defined flaked or bizarre character. In this country the tulip can be grown for increase more successfully than the hyacinth, as the native soil appears better adapted for the former than the latter. In some of the London parks the great majority of the early tulips which are employed for decoration in spring are carefully looked after when lifted; they are put away carefully in trays of fine ashes in a cool room during the summer, and then examined as planting time approaches, and used for filling the beds. A tulip bulb flowers once, and once only; it has then done its work, and perishes. When a single leaf only is put forth by a tulip bulb the cultivator knows it will not bloom. In the tulip-growing districts of the midlands and north such are technically known as "widows," and not until they throw a second leaf is there hope of an inflorescence being developed.

THE DRY WINTER OF 1897-8.

IN a most interesting report upon the average yield of rain and snow during the five winter months from October to February, as against the fall during the winter of 1897-8, Mr. G. J. Symons, F.R.S., shows very clearly that the land is in need of a considerable amount of moisture. The average total amount of moisture falling during the five months mentioned, taken over a period of forty years, is 10·93 inches, whereas the fall in the winter just ended only totals to 5·62 inches. This is consequently about half the average fall, and on only two occasions since 1858 have there been drier winters, these being 1879-80, with a fall of 5·02 inches, and 1890-91, with a total of 5·31 inches. It is further shown that as in two only of the fifteen individual months was the average fall exceeded, the droughts are due rather to persistent dryness month after month, than to excessive drought in any one or two months. As the wells and underground water supplies are largely dependent upon the percolation of winter rains, it is obvious that such an extremely dry winter is of serious importance to the general body of cultivators, and to residents in the country who obtain their supplies of water from comparatively shallow wells. With a view to determine whether this dryness is local or general throughout the country, Mr. Symons has selected stations well distributed over the country, and at each of which observations have been continuous for at least eighteen years. He then proceeds to give for each of them the average rainfall for the five months, October to February, for the ten years, 1880-89, the actual fall in 1897-98, and the percentage which these last figures are of the above-mentioned average. For the purpose of showing how far the rainfall for the past winter differs from the average it will suffice to give the percentages, which are as follows: Tenterden, Kent, 46; Camden-square, Middlesex, 51; Boston, Lincoln, 51; Bury St. Edmunds, Suffolk, 52; Hitchin, Herts, 52; Hesley-hall, Nottingham, 58; Addington, Buckingham, 58; Ross, Hereford, 62; Alton, Hampshire, 62; Blandford, Dorset, 63; Woolstaston, Shropshire, 65; Newcastle-on-Tyne, Northumberland, 65; Stroud, Gloucester, 65; Hull, Yorkshire, E., 72; Launceston, Cornwall, 72; Manchester, Lancaster, 96; Skipton, Yorkshire, W., 120; and Seathwaite, Cumberland, 127. From a careful examination of the figures here given the facts come out quite clearly. They show that in the north-west of England there has been a wet period, the excess being equal to 20 per cent. in West Yorkshire, and to 27 per cent. in Cumberland. On the other hand in the south-east of England the rainfall has been very short. East of a line drawn from Spurn Head to the Isle of Wight the amount of rain has been about half the average, the absolutely lowest value being at the most south-easterly station. This is a striking example of a feature in the distribution of rain to which Mr. Symons has on several occasions called attention, namely, an oscillation due presumably to differences in the distribution of atmospheric pressure, whereby wet periods in the south-east of England occur with droughts in the north-west of Scotland, and *vice versa*. The balance may be restored within the next few months, but there is no evidence that the drought has yet ceased, and it is, therefore, desirable cultivators should recognise the fact that over the greater part of England the soil contains considerably less than the average quantity of moisture, and also the necessity of conserving the soil moisture to the fullest possible extent by the use of mulching, keeping the surface soil well stirred, and other means familiar to those experienced in garden management.

Decline in Gardening.—Mr. Bryant Sowerby, secretary of the Royal Botanic Society, has been giving a correspondent of the *Daily Graphic* some particulars of the arrangements that have been made for the teaching of gardening in the society's gardens, Regent's Park, and also expressing his opinion of the acquirements of gardeners of the present day. Mr. Sowerby is reported to have informed the correspondent of our daily contemporary that the course of instruction "is to extend over three years. In the first year pupils will be instructed in ground operations, laying out flower gardens and kitchen gardens, and general indoor work in the greenhouses. In the second year the pupils will be taught the duties and knowledge expected of good professional gardeners, from the nature of soils and manures to indoor fruit-growing and the suppression of unnecessary insects; and in the third year they may learn advanced practical gardening." "This," the writer says, "does not appear a very ambitious programme, but it has this great recommendation that any pupil who conscientiously follows it will find himself at the end of three years in a position to earn good wages, for the demand for gardeners is growing, and good gardeners are more rare than good professional footballers." It is not quite clear whether this opinion is founded upon information obtained from Mr. Sowerby, or upon the observations of the writer; but Mr. Sowerby is reported to have said that "Gardening is in a bad way at present. There are only a limited number of gardeners who can do more than rake over the mould; and we could find places for as many competent gardeners as we are likely to cultivate." It cannot be necessary that we should discuss the question as to whether or not a pupil can become "a competent gardener" in the course of three years; for everyone who has any practical knowledge of gardening is familiar with the fact that the time is not more than sufficient to enable him to do more than obtain enough knowledge to make him an efficient journeyman. But the statement that "there are only a limited number of gardeners who can do more than rake over the mould" is so absurd that surely there must be some misapprehension as to the opinion expressed by Mr. Sowerby.

National Chrysanthemum Society.—The adjourned annual meeting of members will take place at Anderton's Hotel, Fleet Street, E.C., on Monday, March 21 next, at six o'clock in the evening, to receive the committee's revised statement of accounts, together with an estimate of receipts and expenses for the current year; to elect a president, vice-presidents, officers, and committee for the year ensuing; to consider certain amendments to the rules; and to transact such business as pertains to the annual general meeting.

Cinchona in India.—At the usual monthly dinner and [illegible] Horticultural Club on Tuesday, the 8th inst., with Mr. Harry J. [illegible] man, a valuable paper was read by Mr. J. A. Gammie, on the cinchona in India, in the culture of which he had been engaged for many years in the Bengal Presidency. Mr. Gammie described the various species of cinchona used, the method of cultivation, and the means adopted through the agency of the Post Office for the distribution of the drug to the various fever-stricken districts. He showed how through extended cultivation its price has been reduced so as to bring it within the reach of all. In consequence of the pressure on our space we are compelled to hold over Mr. Gammie's paper.

Tree Planting on Hampstead Heath.—At the first meeting of the fourth London County Council, the Parks and Open Spaces Committee [illegible] upon the objections raised against the Council for planting trees near Willow Road and Spaniards Road, Hampstead Heath. The committee considered that the trees which had been planted were suited to the heath and would tend to its preservation, and asked that their report be approved. Mr. Bond, M.P., moved, as an amendment, that in the opinion of the Council it is desirable that the trees recently planted east of the Spaniards Road should be removed, and that the Parks Committee be requested to report further as to the reasons which render it, in their judgment, inadvisable to comply with the wishes of the Hampstead Heath Protection Society, as expressed in the letter of Mr. Ernest Lake. Mr. Dickinson seconded the amendment, but after a short discussion it was decided, on the suggestion of Mr. Costelloe, that the report be referred back to the committee.

Black Currant Mite.—An interesting letter has been received by R.H.S. Scientific Committee from Miss Ormerod giving an account of what is being done experimentally at the Duke of Bedford's fruit farm at Woburn, under the direction of Mr. Spencer Pickering, F.R.S. As to the possibility of obtaining "mite-proof" black currants, the only result has been some plants received from [illegible] which she has distributed to the Toddington fruit grounds, to Mr. Speir Newton's farm, Glasgow, and to Woburn. Miss Ormerod has given as exhaustive an account as she could form of the disease in a special appendix to her twenty-first annual report, from the period of its first appearance until the present time. A series of experiments are now being set on foot at Woburn directed to every point which is open for serviceable action, including chemical applications. These will be followed by expert examinations of the contents of the galled buds treated; and with coincident examination of galled buds under precisely similar circumstances, but *not* treated chemically. These experiments will be found detailed in the appendix, pp. 141-158. A conclusion anticipated is that there should be "a difference in broadscale method of growing." Mr. Gordon sent to the meeting sprays of the filbert infested by Phytoptus which he had received from Kent, to show the danger with which the nut crop is threatened. The sprays are erroneously described in the official report as specimens of the hazel nut.

Daffodil Prizes.—Since issuing the schedule of arrangements for 1898, the Royal Horticultural Society has received from Messrs. Barr and Sons, of King Street, Covent Garden, the offer of a silver cup for daffodils, to be competed for at the society's meeting at the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, April 12, open to all amateurs. Notice of entry should be addressed to the secretary, R.H.S. Office, 117, Victoria Street, S.W., and must be posted on or before Thursday, April 7. The particulars of competition for the cup, are "Collection of cut daffodils (polyanthus section excluded), each of the three groups—Magni-coronati, Medio-coronati, and Parvi-coronati—being represented, the flowers to be arranged in bottles which will be provided by the R. H. Society. Not less than forty different varieties and not more than three bottles of any one sort to be staged. Correct naming and elegance of arrangement will be taken into account."

Inner Temple Gardens have been preserved from the builder or from further enclosure by the rejection of the Bill, promoted by the Benchers, seeking powers to extend their buildings in King's Bench Walk southwards. The Bill came before a Select Committee of the House of Lords recently, and was strenuously opposed by the Corporation of London, the London County Council, and the District Railway Company. The Committee decided, after hearing evidence, that the preamble was not proved.

Orchid Roots with Fungus.—With reference to the specimens brought to the last meeting of R.H.S. Scientific Committee, Mr. Murray, of The Gardens, Oakwood, Wylam-on-Tyne, writes to say that he is "convinced that it is from no other cause than from the want of air, or, rather, circulation of it among the plants." In a previous communication to Mr. Douglas, he expressed agreement with Mr. Veitch's interpretation, but not quite in the manner he explained, for he observes, "I ventilate the houses day and night with the ventilators, . . . but the air upon the stages, or, rather, above the stages, where the plants are standing close together, travels very slowly, even with ventilators open, in comparison with that around the centre staging, as plants thereon seldom show signs of fungus."

New Zealand Apples to the extent of five thousand cases are to be shipped from the Canterbury district to London. The packing and shipment will all be done under the supervision of New Zealand Government officials.

The Wimbledon Horticultural Society recently presented its [illegible] secretary, Mr. W. Thomson, with a nearly life-size and quite life-like portrait of himself, prepared by Messrs. Russell and Sons, as a mark of the esteem in which he is held, and as some recognition of the valuable services he has rendered to the society for many years. The presentation was made by Mr. Crocker, the president. We understand that the next summer show at Wimbledon will be held in the grounds of Canizaro House, Wimbledon Common, the residence of [illegible] Mitchell.

The Formation and Properties of Soils forms a question of the widest interest to horticulturists of every grade, consequently we may anticipate a large attendance at the lecture on this subject to be delivered by Mr. J. J. Willis at the meeting of the Royal Horticultural Society to be held on March 22. Mr. Willis has the faculty of placing hard scientific facts before his audience in a most interesting manner, and few have had more opportunities of observing the composition and value of soils.

Carnations and Picotees in the Midlands.—The Midland Carnation and Picotee Society sets an example which may be commended to the notice of societies generally associated with floriculture as worthy of imitation. Instead of hiding their light under the proverbial bushel, the committee very properly take the steps necessary to show the world of floriculture that it is actively engaged in the performance of the work for which it was founded, and that it is fully justifying the views that were given expression to seven years since by those to whom belongs the credit of establishing it. We have received the seventh annual report, and from this we are pleased to learn that, notwithstanding the unfavourable weather experienced on each of the show days the society was able to increase the balance at the bankers'. The report contains a sketch of the work during the past year; the list of the prizes offered for competition at the exhibition to be held at the Botanical Gardens, Birmingham, on July 27 and 28 next, the rules, a list of the finest exhibition varieties, and a paper by Mr. Robert Sydenham on "Carnation Culture." Fifty-two classes are provided in the schedule, and the prizes include a ten-guinea challenge cup for competition in the amateur's classes, and a ten-guinea cup for trade growers. We are pleased to see that border carnations, and arrangements of carnations for personal adornment and the decoration of the house, receive liberal encouragement without there being any diminution in the awards for florists' flowers.

The San Jose Scale (*Aspidiotus perniciosus*) was the subject of some discussion at the monthly meeting of the Entomological Society, owing to its reported occurrence in Great Britain. Mr. R. Newstead stated that during nine years' work on Coccidæ he had never once met with this species among scale-insects taken in this country and sent to him for identification. It was impossible even for an expert to distinguish it, without careful microscopical preparation and examination, from among the thirty or more known species of Aspidiotus, and any attempt to identify it on imported fruit by naked-eye observation, or with a hand-lens, was therefore quite impracticable. The risk of its distribution by being imported on fruit was small. There was, however, much more likelihood of its introduction on plants. At the same time, he saw no reason to suppose that it would be more injurious in this country than the common *Mytilaspis pomorum*. In America the San José scale had several generations in the year, sometimes as many as five, but in this country it would probably conform with the habits of all other scale-insects at present investigated, and become single-brooded. This may be somewhat reassuring, but the probability of the pest not producing more than one brood annually does not in any way render it less necessary to take steps to prevent its introduction into this country.

The Structure of Cycads was discussed at a recent meeting of the Linnean Society by Mr. W. C. Worsell. In the course of his address he pointed out that in cycas the conduplicate vernation and arrangement of the bundles in the fleshy hypogœal cotyledons, the secondary extrafascicular rings, the concentric cortical strands, and, in one species, the peculiar concentric structure of the leaf-traces, in the stem, and in the hypocotyl some curious concentric strands running obliquely out from the cylinder, and, in a small seedling, the secondary vascular cylinders lying outside the normal stele; in the seedling of Stangeria paradoxa the small primary concentric bundles in the stalk common to the two cotyledons, which both higher up and lower down become collateral, and in the adult stem the occurrence of a secondary concentric strand in the periphery of the cortex, which appeared to be the remnant of a once normal system of nude strands; and in Ceratozamia mexicana the vertical succession through the pith of a large stem of effete peduncular cylinders, the peduncles which successively terminate the stem being in turn pushed to one side and their basil region enclosed by a lateral shoot which continues the main vegetative axis. In conclusion, Mr. Worsell endeavoured to demonstrate that certain characters in the vegetative structure of these plants showed them to be nearly allied to, or descended from, certain fossil fern-like plants, notably the Medulloseæ, and these characters were: the extrafascicular zones in the stem of cycas, which really represent the outer portion of the flattened concentric strands in the stem of the Medulloseæ, the inner portion of which has died out, and all the various concentric structures above mentioned. For the type of structure prevailing in the ancestors of the cycads would have been the concentric, whereas in their descendants it is the collateral. The significant outcome of this study is to form, in the vegetative characters of these plants, a connecting link, over and above that already afforded by the discovery of spermatozoids in cycas and ginkgo, between "flowering" and "flowerless" plants. Dr. D. H. Scott, in criticising the address, referred to the importance of certain facts which had been elucidated by the author, which he himself was able to confirm.

Dr. Wilhelm Pfeffer, professor of botany at the Leipzig University, has been invited by the Royal Society to deliver the Croonian lecture. This lecture has for its subject "The Nature and Significance of Functional Metabolism in the Plant," and is being delivered, in German, as we go to press (March 17). Dr. Pfeffer is well known to botanists, especially for his researches in the physiology of plant life.

National Horticultural Society of France.—The following gentlemen have been elected by this society presidents of the undermentioned sections: floriculture, M. Savage; fruits, M. Coulombier; ornamental and useful trees and shrubs, M. Croux; chrysanthemums, M. Lemaire; and roses, M. Maurice de Vilmorin.

A MORNING MIXTURE.

Diluculo surgere saluberrimum est.

Why do not gardeners read gardening papers? This is a question which has often puzzled me. Perhaps someone may respond that gardeners *do* read the papers, so there is an end of the matter. But I venture to think that the number of regular readers is comparatively limited, and the reason why I have come to this conclusion is that when, in conversation, I have brought up a topic under discussion in one or other of the journals, neither chiefs nor staff were able to respond, because they "haven't noticed what's been said." Understand me, I am not referring to the leading gardens, which are few, but to medium gardens, which are many. I daresay the principal explanation of this fact is that reading is looked down upon with a certain amount of contempt by "practical" men, forgetting, as they do, that it is usually the heads, or, in other words, the most able and practical members of the profession, who become teachers.

I do not want to be prosy, and I have no present penchant for moralising. Neither ever does much good. But common sense ought to tell a man that if he has the chance of getting the experience of a dozen or more first-class cultivators for two or three pence a week, he is as much an ass as ever the law was if he does not take it. I thought this rather more strongly than usual when, on the first Friday in March, an old friend came along the drive in a new spring suit and tumbled himself with a heavy thud into the letter-box, thence sprawling, by reason of his corpulency, out on to the mat. To abandon this subtle allegory, let me say at once that it was the Gardeners' Magazine Spring Number. What though it contained food for differences of opinion on detail in its numerous articles. Was it any the less valuable? Not a bit. To my mind, the man who finds food for the exercise of his critical faculty is the one who gets the most enjoyment out of his gardening and out of his reading. Nothing gives me greater pleasure than to vigorously kick any contributor whom I think I have cornered, unless it be to get an equally vigorous kicking in return. Learn, my excellent young friends, to kick and to receive kicks, both with a kindly heart.

I am going to wander through the forty well-packed pages of the spring Gardeners' Magazine, deliberately, but not of malice aforethought, in search of kicks. It is rather unlucky, though, that the first contributor with whom compliments have to be exchanged is Mr. Wythes, for that portly professional is one of the heavy-weights. There is none of the light comedian or juvenile lead about the Syon chief. He is the heavy man, and, as I have before remarked in these pages, enjoys the rare distinction of Peter's approbation. There are, however, one or two points in his communication on raspberry culture which are open to criticism. In the first place, he appears to deprecate trenching in dealing with light soils. It is just on such soils that trenching is most needed, because the deepening and pulverisation of the ground secures more moisture. The remark that deep trenching means putting the good soil out of the reach of the roots has caused Peter to shake his head; he clearly expected something better from Mr. Wythes. We are believers in trenching, and sustain our belief by solid work, but we take care to so arrange our system as to put the good soil—no matter where it was originally—where the roots are. There are many modifications of plain trenching.

I should like, too, to say a word as to the advice given to cut out the old canes directly the fruit has been gathered. As a matter of labour economics, to coin a phrase, this is, generally speaking, almost impracticable, because the work would have to be done when every available hand is fully occupied with pressing duties. Mr. Wythes writes from the point of view of the private gardener, into whose sphere those worrying economics do not come. The man who is trying to make money can find more fruitful work for his hands in August than raspberry pruning. Nor do I quite look eye to eye with Mr. Wythes in respect to the intrinsic merits of the process. Is it very far-fetched to suppose that the highly elaborated sap of the older canes nourishes, in descending, the basal buds which are the foundation of the following year's canes? I am more and more inclining to the view that it does, in a measure, serve that purpose, and that October is a better month than July or August for pruning, quite apart from the fact that labour is then becoming available.

It is not often that I read an article of Mr. Beckett's with disappointment, but when, under the heading of "Vegetables for Exhibition," I found two-thirds of his communication about early potatos dealing with early forcing, I must confess to a slight tinge of it. There are few of us, probably, whose modest competitive efforts with the noble tuber call for ten-inch pots and heated pits. Perhaps one of these days the Luxian potatos (*pace!* Mr. Prinsep) and other forced produce will be carrying off a gold medal at the Drill Hall, but the time is not yet. However, in the latter part of his communication, Mr. Beckett gives we poor outsiders a little advice, and capital it is, as I can testify, particularly the recommendation to use spent, crumbly manure and leafmould in planting. It ought to be quite obvious that in the case of such a vegetable as the potato, heavy dressings of damp, rank manure must be of questionable value. The stuff may and does give a heavy crop, but the tubers are not of the beautiful texture and speckless skin which we covet. I have never had a more even and clean lot of tubers than when I have mixed leafmould and burnt rubbish, the latter with its rich stores of potash, and spread in the drills.

In the latest of his pleasant articles on "Ferns," Mr. Druery describes himself as a fern "maniac," and hints at a leaning towards the giving away of seedlings as souvenirs. This would support the view I have always held, namely, that there is much method in his madness. And if a consignment of seedlings reaches me per the editor at an early date, I shall hold the view more tenaciously than ever. To the ordinary horticulturist there is a certain coldness and "deadness" about ferns which prevents him opening his heart to them as he does to flowers, but it cannot be denied that some of the crested forms are exquisitely beautiful. There is something, too, to be said for the attraction they exercise—far transcending that of gaudy flowers—on refined minds. There were many people who could make nothing of the original Gulliver until others, more acute, ferreted out the meaning for them. Perhaps the "new Gulliver" is also rather too much for some of us at times, but we shall understand him the better when our intellect departs from the narrow grooves and assumes "cristation."

Mr. E. Molyneux deals some staggering blows at the generally accepted ideas on the fruit question. In particular he traverses the direct advice given editorially in the MAGAZINE—and not there alone—to plant late, long-keeping sorts for market. If the good people of Southampton will not buy average fruit of Cox's Orange Pippin and Bramley's Seedling, Mr. Molyneux should send it to parts where they have some elementary knowledge of real merit in fruit. I did not think the English town existed where American or Tasmanian varieties are better known than Cox's. What Southampton is thinking about to have a prominent horticulturist like Mr. Molyneux at its gates and yet remain in ignorance of our premier dessert apple passes comprehension. But is our friend himself consistent? He condemns Bramley's because it is a late keeper, but commends Lane's Prince Albert, which is another of the late section. Surely the fact that in autumn after autumn gluts bring down prices to a ruinous level shows the danger of advice to grow sorts that must be cleared six weeks before Christmas. Generally foreign competition is more severe in the early part of the season than towards the end, and the result of this is that our large growers are putting down more and more late sorts. Are they all wrong? I doubt it. In any case, it is highly probable that they will want stronger proof of it than the experience of a cultivator who only began planting for market eight years ago.

There is no article in the spring number more interesting than that of Mr. Geo. Harris on allotments in the north. Few writers and few tradesmen give special attention to the rapidly increasing army of allottees, although the evergreen Mr. Cannell is an exception among the latter. The enterprise of the energetic northerners quite shames the apathy of the south. The taking of hundreds of acres and cutting them up into small plots bespeaks real progress. What a pity it cannot be done all over the United Kingdom. Or rather, what a pity there is not sufficient public spirit amongst the people to get it done, difficult or easy.

I thought I should catch it from Mr. Prinsep about those potatos, and I have. It was Peter who egged me on, and when I had partly recovered from the shock I summoned the tempter to my presence, and demanded to know what I was to say in reply. To begin with, Peter displayed a virtuous wrath. He feels himself at full liberty to question my horticultural omnipotence, but no one else must do so. What I have to say is not infrequently wrong to him, but if the world at large ventures to flout me it is characterised as a piece of gross presumption. Having relieved his outraged feelings on this score, Peter delivered the following withering reply to Mr. Prinsep.

"Mr. Prinsep thinks he's wonderful clever, I can see. Perhaps he's been growing potatos longer'n what I have; I daresay he has, according to what he says. Well, if he has, why is it that he grows six hundred of other people's varieties [Steady, Peter, sixty, not six hundred—LUX], and other people don't grow none of his? We've got some here of Mr. Carter's, and some of Mr. Daniel's, and some of Mr. Sutton's, and some of Mr. Webb's, but we haven't got none of Mr. Prinsep's. What do people like them want to get in his way for? Impudence I call it. Now, I should like to ask this gentleman a question or two. He drops in remarks about growing the heaviest crop ever lifted in England, and producing thirty or forty tons an acre. Oh! Perhaps he's grown a bigger crop than my grandfather on my mother's side; but if he has, why doesn't he tell us all the particulars? I can produce mine if he can produce his. If he can grow forty tons an acre, why doesn't he make his fortune and retire? Let him send all particulars, and have 'em published. Now, I should like to ask him another question. Says he, 'It is not actually necessary to put the tubers on their ends till the winter is half over.' Well, what's he want to put his on end in August for? I suppose he does it because it isn't necessary. Now there's ——"

At this stage I interrupted Peter, and pointed out that enough had been said for the moment. By the time Mr. Prinsep has digested the above onslaught, and answered the questions contained in it, more can possibly be said with advantage. My excellent critic is quite right that I am not thin-skinned, and he, in his turn, will not mind my asking him for particulars of the biggest crop in England. What was the variety? What was the actual extent of ground? What manure was used? What steps did he take to check measurements and weighings, so as to prevent accidental errors? Having disposed of this he may, as Peter suggests, tell us why he starts set-preparation in August when it is not, in his own opinion, necessary.

LUX.

Children's Prizes for Flowers.—This year the Wood Green Horticultural Society has provided classes for plants in pots and cut flowers, in which the competition will be open to the children of members. Not only does the society provide the prizes for children, but it has supplied the intending competitors with seeds free. The seeds were supplied in collections of six packets each, one collection comprising seeds of plants suitable for cultivation in the open, and the other of seeds of plants to be grown under glass.

APPLES IN HAMPSHIRE.

WHEN alluding to the kind of trees to plant I omitted to say I planted six-feet standards thirty feet apart, and bushes fifteen feet. Thus we have bush trees in one row above fifteen feet wide, and one bush between the standards in the next row fifteen feet from the row of bushes. Standard trees may be all very well for the future of thirty years, but if I were to plant again I should have bushes only. With view to utilising the space thoroughly, five years since I planted some hundreds of maiden trees of approved varieties of such sorts as Lane's Prince Albert, Lord Grosvenor, Benoni, Worcester Pearmain, and Bramley's Seedling. Between the rows at fifteen feet these maiden trees were planted, and eight feet from tree to tree. At the present time that part of the orchard is now fully grown, the trees almost touching each other. The fruit obtained from these added trees has perhaps hardly been commensurate with the outlay, but here are the trees, and with a little more space would develop into handsome bushes in a short time. The preparation for planting was done in the following manner: six weeks previous stations or holes were taken out four feet square on the surface, and two feet deep, in preference to trenching the whole, as we were wishful to retain the grass between as much as possible. The soil is somewhat peculiar and required dealing with in a systematic manner. The top spit one foot deep is a nice friable loam, below for three feet lies a hard tenacious soil, not absolutely clay but a near approach to it. Owing to its being freely intermixed with large flint stones it cannot be called wet land. In digging out the holes the turf was laid on one side, the top spit by itself and that below by itself. The bottom of each hole was broken up six inches deeper to assist the free percolation of the water from heavy rains. The soil was returned to the holes in an opposite manner to how it was taken out, thus keeping the surface soil—which is the best—in the same position. Mounds six inches high were formed on which the trees were planted, with the object of keeping the roots as near to the surface as possible. The turf was utilised to plant each tree in with the addition of two or three shovelfuls of decayed vegetable refuse and wood ashes with a small portion of half-rotted manure. No manure was used below the roots, thinking this would be an incentive for the root to go deeply in the soil. Mulching and staking of the standards was done at once.

The vexed question of pruning the newly-planted trees was my next thought. Knowing there were several opinions as to the advisability of pruning at once as against non-pruning, I determined to put the two systems to a practical test, although my mind was already made up as to which was most likely to succeed. In February I cut back the bulk of the trees to a few eyes on each shoot, my object being to lay a foundation to increase the size of the trees, starting the bushes as near to the ground as the shape of the trees would admit. The result of this close pruning was to induce a vigorous growth the first year by curtailing the energy of the tree to a limited number of shoots. In some cases I simply removed the point of the shoots, the result being but scanty growth and clusters of flower buds on the shoots retained. In other instances no pruning was done at all, the result being scarcely any growth, and in some instances bloom-buds formed on the point of each shoot, and thus checked future growth. Certainly in the case of Ecklinville this was so, and in addition to the cluster of buds at the point of the shoot many more formed on other parts, and, as I suspected, from the two latter methods of pruning the base eyes remained dormant, and in many instances died entirely. For the above reasons I neither practise nor advise either method, as it is growth we require the first season, and not fruit blossoms. The advocates of non-pruning the first year argue that to give two checks—planting and pruning—at one time is not a good system. The latter ought to be deferred for a year until some recuperation has taken place in the tree as the results of interfering with the roots. Surely, then, to cut a tree hard back after one season's growth is a much too slow policy in these go-ahead days.

My practice of pruning since has been to simply shorten the season's growth sufficient only to ensure sufficient base eyes to burst into growth and furnish the trees properly and preserve their shape. I am not a believer in the hard-pruning principle after a tree has become established. I have no hesitation in saying that, with few exceptions, it is not necessary to root-prune apple trees to induce fertility if space is available to allow a sufficient extension of the branches. Not so when the trees are closely pruned annually.

A few words as to the mulching of the newly-planted trees may not be out of place here. I am a firm believer in the value of mulching for conserving the moisture about the roots during dry weather, but this may be carried to excess. A thick mulching of manure during the month of May prevents the sun warming the soil, and, of course, the roots also. This I hold to be a mistake, as solar heat at that period encourages free root action, which means successful progress. My plan is to remove the mulching on one side for a time to admit of the sun exercising its influence on the soil, and should the weather remain long enough dry to parch the surface soil the manure is returned.

If three-year-old trees are planted many will develop blossoms the first season; it is time well spent removing these, thus concentrating the whole energy of the tree into the growing shoots. I am a firm believer in the practice of summer pruning apple trees. It is not possible to obtain heavy crops of fruit from immature branches. If all surplus shoots are removed they do not incommode the penetration of sunlight, air, and wind, all influences to wood maturation. If these surplus growths are removed at the winter pruning as a necessity, my argument is, why not dispense with them in July, or at the latest in August? Little remains now to be said in this article, which I fear is already too long, but which might have been extended, and perhaps with interest to some of your many readers.

Swanmore Park Gardens. E. MOLYNEUX.

Some Roses of 1896.

Bladud, H.P. (Cooling and Sons).—This rose is rightly described as "an enlarged Mademoiselle Bonnaire." Its colour is white, with blush centre, full, but not very perfect in form, and lacking a high centre. Judging from the thinness of its petals, he blooms would soon damage in wet or damp weather. It has not, up to the present, been very well staged, but it may improve as time goes on. It is, however, a most distinct variety amongst exhibition roses, and is a seedling raised by the late Mr. Henry Bennett.

Ellen Drew, H.P. (A. Dickson and Sons).—This rose is a distinct sport from that old favourite La Duchesse de Morny, which was introduced as far back as 1863, and still holds its own. As everyone knows, La Duchesse de Morny has its particular years, when, from some reason or other, it comes remarkably good, being seen in fine form in all the leading stands, and then for the next four or five years it seems to be lost sight of altogether, like the pale-clouded yellow butterfly. It is not at all improbable that Ellen Drew, following its parent, will behave in the same way, so that even if it does not come to the front in 1898, that is no reason why it may not do so in 1899, or subsequent years. La Duchesse de Morny is bright rose, Ellen Drew is silvery pink, a not altogether desirable colour, but nevertheless distinct. In wood, foliage, and form it is identical with the variety from which it sported. Taken altogether, it is a good, new rose, and one of which we shall probably see more in the coming season.

Lawrence Allen, H.P. (Cooling and Sons).—This promising rose can hardly be called a "native of Bath," for it was one of the late Mr. Henry Bennett's seedlings, purchased by Messrs. Cooling, and sent out by them last year. I was first attracted to this rose by seeing a remarkably fine stand of it exhibited by the introducers at the Bath rose show in 1897, and have seen it since at other exhibitions, generally well staged. It is in colour a soft pink, something, but not altogether, like Her Majesty, with similar wood and foliage, perfect in form, cupped globular, and when well established will probably prove to be one of the best hybrid perpetuals sent out for many years. It would not be at all surprising to see it taking a leading place in next season's exhibitions. If the flowers staged at Bath had been exhibited in the class for new seedlings at any of the National Rose Society's shows, it would doubtless have gained a gold medal. Messrs. Cooling and Sons are to be congratulated upon Lawrence Allen.

Muriel Grahame, T. (A. Dickson and Sons).—There has been so much discussion about this rose that little more need be said. I was somewhat doubtful as to the good qualities of Muriel Grahame last year, owing to there being what seemed two varieties, and knowing its history, and that it was another sport from Catherine Mermet, I questioned whether the sport was fixed. But after the splendid examples staged last year, it is evident that those who supported its claims were quite justified in doing so. Up to the present we have not been able to do much with it, for it makes but weak growth, and does not propagate easily from buds. But then our climate is not suitable for teas, especially of the Catherine Mermet strain. If Muriel Grahame is as vigorous in constitution as it is grand in flower, it will rank with the very best of teas, and run Maman Cochet hard for the premier position.

Madame E. Resal, China (Guillot).—This variety as staged by Messrs. Paul and Son at the Manchester rose show last year, in an interesting group of decorative roses, is highly promising. The flowers in clusters made a very pretty bunch. The colour seemed to vary in shade, so that it is not easy to describe it. It was a kind of coppery-red, something like that old rose Ophirie. As there was no restriction in the Manchester schedule as to the number of trusses to a bunch, it was impossible to judge correctly of its free-flowering qualities. We shall see more of it probably when it becomes better known to the cultivators of decorative roses. Messrs. Paul and Son describe it briefly as "rose, shaded with orange, very free, in the way of Laurette Messimy."

Madame Jules Finger, H.T. (Guillot).—Mr. Benjamin R. Cant had a good flower of this variety in his stand of new roses at the Crystal Palace show last year, and it was worth making a note of, but it is so like the generality of the new hybrid teas, many of which appear to suffer from anæmia, that one cannot at present call it distinct. It is described by Messrs. Paul and Son as follows: "Flowers large and full, creamy-white, shaded with pink, distinct and novel;" but both they and other trade-growers, in speaking of its growth, designate it as "moderate."

Queen Mab, China (W. Paul and Son).—This is a charming decorative rose, and, like most of the Chinas, appears to be very free-flowering. It is something after the style of Ma Capucine, and therefore will doubtless soon be popular with the general public. The raisers staged some very effective bunches of it last year, notably at Manchester, and their description of the rose is as follows: "This variety belongs to the decorative and button-hole class of roses, of which Ma Capucine and Madame Laurette Messimy are good examples. It is, however, perfectly distinct from all others, and is much superior in its sturdy habit of growth and the substance of the petals of the flowers, the latter quality enabling it to last longer when cut than any other rose we are acquainted with. The colour may be described as soft rosy apricot, the centre of the flowers shaded with orange, and the outside tinted with rose and violet; it blooms with extraordinary freedom, and is most excellent for garden decoration and for cutting."

Robert Lebaudy, H.P. (Leveque).—This is a continental introduction, and at present but little known. A few flowers of it were staged in the stands of new roses last year, and these were generally good; notably a bloom at Wolverhampton. Probably, whenever it appeared in the stand, it attracted attention, because it was a distinct red, a decided red, so rare to find amongst the new seedlings. Mr. Benjamin R. Cant thinks it a good rose, and so, not having as yet grown it myself, although we hope to stage it this coming season, it will be well to give his description: "Vermilion red, shaded with purple, large and full, fine flower, and very promising."

Souvenir de Madame Eugène Verdier, H.T. (Pernet-Ducher).—The colour is white, with a faint suggestion of yellow; the flowers are of good size and form, and the growth strong. Some noteworthy examples of it were staged at last year's rose shows, and it has every appearance of being a good rose. The raiser's description is: "Very vigorous, flowers large, very full, and perfect form; colour electric white, shaded saffron yellow. Very fine under glass."

Tom Wood, H.P. (A. Dickson and Son).—We have grown this variety last year on maiden plants, and consider it a good rose, although one cannot help wishing its colour was a little brighter; it is Cheshunt-hybrid red. It has been staged by the raisers, but somehow it lacks brilliancy even with them. I like its habit, for it is strong and robust, producing large, well-shaped blooms, flowering freely. Messrs. Dickson state it to be "a variety of great merit, either for garden decoration or exhibition purposes. The colour is cherry-red, petals large, shell-shaped, and of immense substance; flowers very large, full, and perfectly formed; growth vigorous, and of free branching habit, flowering freely and continuously from early summer until late autumn; the foliage is most distinct, and almost mildew proof."

A Correction.—With reference to my remarks in the Gardeners' Magazine of January 29, upon hybrid tea Clara Watson, knowing it to be sent out by the late Mr. George Prince, and named after Miss Watson, I questioned the statement of Rev. D. R. Williamson in "The Rosarian's Year Book," that this rose was raised by the late Mr. Bennett. I beg to apologise for so doing. The editor of this Year Book writes to me as follows: "The late Mr. Henry Bennett left behind him some pans of seedling roses; these were bought by Mr. George Prince, Messrs. Cooling and Son, and other nurserymen. Clara Watson was one of Mr. Prince's lot." Joseph H. Pemberton.

Young Vines and Cold Borders.

As the time for planting young vines has again arrived, there are a few matters in connexion with this operation to which I would draw the attention of those about to undertake such work. Generally, when a new vine border is to be made, the turf from some old pasture land is cut in the autumn and carted home in dry or frosty weather. Often when the turves are thawed they are chopped and mixed with such things as basic slag, kainit, wood ashes, lime rubble, &c., and the border immediately formed of this mixture. Now, were a thought given out as to the temperature of this mass, and the temperature the young vine roots are in before being planted, few would care to transfer the one to the other until the temperature of the border was raised. Several instances of mishaps have come to my knowledge, and to no other cause could they be traced than a cold border.

In one case the condition was exactly as described, and the temperature of the border could not have been above 45 degrees, if that, for the work of making was finished a few days before the vines were planted. The vines did little good for two years, but afterwards grew away, and are now in excellent health. The young vines were started in a house with a minimum temperature of 55 to 60 degrees, and as the pots were surrounded by the same degree of warmth, the check they would receive on their roots being placed in a soil so much colder than they had previously enjoyed, and just at the time they were required to support growth, proved too much for them. Although the soil was carefully washed from the roots in tepid water and disentangled, yet a certain amount of damage was done, which would in no wise improve their powers of withstanding the shock occasioned by the cold border. During the first year, the growth they made seemed to be limited to the amount of store food the plants contained. In the autumn only a few young rootlets were found. The second year after planting, most of the vines looked better, but real progress was not made until the third year. Since then they have done exceptionally well.

In the case of anyone having a cold border and young vines ready for planting, the question arises, how is it to be warmed? When there is command of hot water, the difficulty might be overcome by giving it a few soakings with the water at 100 degrees, or even more, till a temperature of something like 60 degrees was obtained in the border. By allowing the water to drain for a couple of days, and then planting the vines, using, if necessary, some soil previously warmed in the house for covering the roots. The soil taken out for the purpose of planting could be placed on the top of that immediately covering the roots, and the space occupied by the roots again watered with water at, say, 80 degrees. To retain the warmth in the border, place a bed of fermenting material upon it two feet deep. This bed will also assist in maintaining a warm, moist atmosphere for the canes, as well as materially influencing the growth of their roots. J. Riddell.

The Almond.—This very beautiful flowering tree, of which there are many examples in my neighbourhood, has been having a bad time of it this season, because of the sharp frosts and keen biting winds that have prevailed; hence the blooms have had colour taken out of them, and they have been scorched. Should anyone, however, deprecate planting the almond for this reason they would act very foolishly, because the tree does bloom beautifully and unharmed three seasons out of four at least, if not oftener. That fact, too, is worthy of notice, because some people seem, in relation to fruit trees, never to tire of preaching the importance of getting late bloomers, whereas time of blooming seems to have little to do with danger from frosts, as these so often do more harm late than early. We have good reason as a rule to be very grateful to the almond for the exceeding beauty it gives to our shrubberies and gardens in the very early spring, as well as for its lovely odour.—A. D.

HARDY SPRING FLOWERS.

ALTHOUGH the setting in of cold weather during the last few weeks has somewhat retarded many spring flowers, and unfortunately somewhat spoiled some less hardy ones, such as the beautiful Rhododendron præcox, Megasea Stracheyi, and others, there is now nevertheless a fair show of seasonable hardy flowers, and beds which were bare a few days ago are now a mass of bloom. Of bulbous plants, Chionodoxa Luciliæ and C. sardensis are no doubt the most showy of the squill tribe. No plants increase more readily or are so easily grown as these two species of chionodoxa, it being almost impossible to find every small bulb of them in clearing a piece of ground. What with bulbs left behind and seedlings which flower the second year, these plants are everywhere to be found, and no matter whether the ground is turned over ever so deep, they will manage to come through. To acclamatise chionodoxas and have them particularly fine, I should recommend the following method of culture. Plant the bulbs as early as possible in the open ground, not shallow but about twelve to eighteen inches deep. Such bulbs will not be the earliest, but, on the other hand, will neither suffer from frost, which sometimes spoils the early-flowering ones, nor from exceptionally dry weather, and so die off prematurely; and there is the advantage that when the leaves have disappeared, which is usually in May, some other plant can be placed on the top of them, without interfering with the bulbs. There are, at present, about five species of chionodoxa known: C. Luciliæ with sky-blue, star-shaped flowers with light centre; C. sardensis with smaller deep blue flowers; C. gigantea (C. grandiflora) with large violet blue flowers being easily distinguished from C. Luciliæ by its broader leaves, few but large flowers, and broader segments; C. Alleni is synonymous with C. grandiflora; C. Timoloussi, a small-flowering later form of C. Luciliæ, and hardly worth cultivating; and C. cretica, a small-flowered species with pale lilac or lilac-purple flowers, remarkably free; there is also a fine white form of this. C. nana is a dwarf violet or purple flowered species, but is not so easily grown as the more showy C. Luciliæ, C. sardensis, and C. grandiflora. Of C. Luciliæ, C. sardensis, and C. grandiflora there are now pure white forms in cultivation, lacking, however, the vigour of the types.

Scilla bifolia, although by no means as showy as the chionodoxa, is a remarkably handsome plant when well grown; bulbs should, however, not be left out of the ground for many days, and deep planting as in chionodoxa should be adopted. The flowers of the ordinary Scilla bifolia are small, star-shaped, and purple blue, the pedicels being usually purple or brownish; S. bifolia grandiflora has larger and deep coloured flowers; S. bifolia taurica is closely allied to S. bifolia grandiflora, but has a denser raceme, and the stamens are brownish purple; Scilla bifolia Whittalli differs from the ordinary S. bifolia in the more numerous flowers longer pedicels, as well as lighter blue colour. S. bifolia has a very wide distribution, and this explains its great variation. S. bifolia alba with pretty, creamy white flowers; S. bifolia rosea with delicate rosy or flesh coloured flowers; and S. bifolia rubra an exceedingly rare plant with deep rosy flowers are all good. Of the latter, Mr. T. S. Ware had a few years ago a stock consisting of about two dozen bulbs, but being attacked by the narcissus fly, imported from Holland with Dutch polyanthus narcissus that were planted near them, they all died excepting one small bulb, and having been dug in deep, this plant has not been moved, and shows no signs of increase. I only know this rare and beautiful plant to be in two other collections in England, and I greatly doubt it being known at all on the Continent out of the Baden-Baden collection.

Colchicum libanoticum is really one of the most handsome of its genus; it belongs to the many-flowered small-growing kinds, and is closely allied to C. montanum, C. bulbocodioides, and C. Steveni, as well as the bulbocodiums; the numerous flowers are delicate rose, flesh-coloured or white. This is a very vigorous growing kind, and perfectly hardy in this country. Sisyrinchium grandiflorum and its white flowering form are the only two which can claim to be really handsome. The grassy-like leaves and scapes are glabrous, about nine inches to a foot high, the flowers being campanulate, of a delicate purple or white; they are easily grown in a sheltered, partially shaded spot in not too heavy soil. Next to Anemone blanda, which has been here in flowers since the first week in January, and is still in bloom, A. ranunculoides is the earliest; the flowers are pale yellow. This species is best grown under trees. Tulipa violacea, of recent introduction, and one of most distinct and sweetest of tulips, is a small-growing species, the leaves being narrow and short; flowers are of a beautiful rosy carmine or rosy violet, rather small, reminding one somewhat of the equally handsome T. pulchella. This is the earliest of tulips, and is flowering now in Mr. Ware's collection planted without protection, and though the sharp frosts of last week have destroyed many flowers, this seems none the worse. Eranthis cilicicus differs from the well-known winter aconite (E. hyemalis) by flowering quite four weeks later. In growth it is taller, the leaves and involucre being more divided, while the flowers are of a deeper yellow. It is a very pretty plant, and far more showy than the ordinary winter aconite. Adonis amurensis, the earliest of adonis, and quite as easily grown as A. vernalis, has leaves finely cut, and large, much-branched stems, twelve to eighteen inches in height; the flowers are large and yellow. This was well figured in the GARDENERS' MAGAZINE of March 20, 1897, p. 169.

The primulas are quite numerous. Primula Allioni from the Maritime Alps, is of slow growth, but its bright rosy lilac flowers are very pretty, and the plant is fine for the rockery planted in fissures or between stones. P. Clusiana has large, carmine, deep purple or violet flowers; being so easily grown, and such a handsome plant, it should be in every garden. P. calycina and P. Wulfeniana run closely into P. Clusiana, and flower also later. In sunny places the handsome Primula minima has already commenced flowering, while in its native habitat, one usually does not meet it in bloom before June. It is of very dwarf growth, seldom growing above half to one inch high; its flowers are, however, large, sometimes as large as a two-shilling piece and rose coloured. It is very easily grown, and on the Alps I have invariably seen it on meadows among short grass at an altitude of 4,000 to 6,000 feet. P. rosea is just opening its fine flowers, and will no doubt be at its best, if the weather remains mild, by the time these notes appear, Dentaria digitata is again commencing to produce its long terminal racemes of deep violet or lilac-purple flowers. This is best grown under trees or in half-shady beds. Corydalis Ledeboureana and C. rutæfolia have pretty, fernlike, glaucous leaves and lilac and purple flowers. They are both easily grown in a sheltered, sunny position in light soil or in pots.

Of narcissi the following sorts are in bloom: N. pallidus præcox, both the large flowering form and the much smaller, though equally handsome form of the mountains; N. minimus and N. nanus, both small Ajax or trumpet species with yellow flowers; N. nobilis, the perianth being primrose with sulphur divisions; N. obvallaris, uniform yellow; N. Golden Spur, and N. Henry Irving, large, yellow. In the house the new bicoloured Narcissus Victoria is flowering, and is undoubtedly a grand acquisition. In shape it is similar to Narcissus bicolor grandis, formerly the finest of the bicolor Narcissi, but this being late and not forcing early is of less value as a cut flower than N. Horsfieldi or N. bicolor Empress. The flower of N. Victoria is also larger, and under ordinary treatment it flowers as early as N. Horsfieldi, and forces even more readily. Being of vigorous constitution, much more so than most of the new trumpet narcissi, and being very prolific, it is bound to become very popular, especially as a cut flower. Beds of this narcissus at Tottenham look very promising, and will soon be in bloom. Crocus biflorus nubigenus and C. Sieberi var. versicolor, two of the prettiest of crocus species, are again in flower, also the handsome C. Balansæ.

G. REUTHE.

ANTHURIUM CULTURE.

THE anthuriums are invaluable for the decoration of our stoves, many of them being worthy of a place for the beauty of their foliage, apart from the spathes. In establishments where ample room is at the command of the cultivator, those species remarkable for their richly marked foliage should be cultivated, as, without exception, they are strong growers, requiring abundance of head room as well as a large receptacle for the roots, such as very large pots or pans, or even in the case of exceptionally large specimens a shallow tub should be used. The roots of all these species run along either on or just below the surface of the soil in which they are potted, therefore a deep receptacle would be quite unnecessary, in fact detrimental to the well-being of the plant. The most beautiful foliaged anthuriums are A. crystallinum, A. Warocquianum, A. Veitchi, and A. magnificum; the spathes of the latter variety, though of no great beauty, are deliciously scented. A. Scherzerianum, and its many forms are indispensable in a collection, A. S. Wardi being one of the best, and A. S. Williamsi, with its pure white spathes forming a fine contrast to it. Other excellent kinds are A. Andreanum, A. Rothschildianum, A. fevrierense, A. ornatum, A. Lindenianum, A. floribundum, A. Rothschildeanum, and these require very careful treatment, not having so strong a constitution as A. Scherzerianum.

Early in the month of March is the best time for repotting the members of this genus, as they commence making their new growth about that time. The receptacles must be quite clean, and be filled to within four inches of the top with clean potsherds, placing over these a few pieces of charcoal, and after that a good layer of the roughest of the compost. The latter should consist of equal parts fibrous peat and loam, with a liberal addition of broken charcoal and silver sand, the two former to be used in a rough lumpy state. Having the soil and pot ready, take the old plant and ball of soil and carefully remove with a pointed stick a portion of the exhausted compost, separating and spreading out the roots on the new soil, placing some compost over them, and slightly mounding it up to the neck or collar of the plant. During the growing season the temperature should range from 65 to 75 degrees, with a rise of ten degrees by sunheat; the atmosphere must be highly charged with moisture, though in the winter months when the plants are also at rest a much lower temperature will suffice, and less atmospheric moisture. At no time, however, must an anthurium be allowed to become quite dry. When the specimens have become established in the new soil and are showing signs of active growth they require copious supplies of water, rain water for preference, which should be at the same temperature as the atmosphere in which the plants are growing. Syringing should be performed twice a day, and water should be thrown on the paths and stages at frequent intervals throughout the day. All those not requiring a fresh shift should be top-dressed with fresh soil after the exhausted compost on the surface has been removed.

The propagation of anthuriums may be readily effected either by offsets taken from the old plants, or from seed. The latter should be sown as soon as ripe in pans filled with finely sifted peat and sand, placing a sheet of glass over the soil; when the seedlings make their appearance put them singly in small thumb pots and place in a light position in a warm moist house, afterwards growing them as advised for the specimen plants. The magnificent contrast afforded by the deep rich green leaves and bright scarlet spathes of A. Scherzerianum and its varied forms cannot be surpassed, and the effect must be seen to be appreciated. The spathes also last for a considerable time in a fresh state either on the plant or when cut and placed in water for house decoration, where they are invariably appreciated both for their beauty and interesting appearance.

H. T. MARTIN.

Stoneleigh.

Relationship of Calycanthaceæ and Rosaceæ.—Dr. B. Longo has been studying the embryology of the Calycanthaceæ, and, according to the "Atti dei Lincei," he has discovered in their ovules certain characteristics forming a link between this order of plants and the Rosaceæ.

PEACHES ON OPEN WALLS.

SINCE the introduction of so much glass into our gardens, it is doubtful if that care is taken to grow peaches out of doors as there used to be in the days of our forefathers. There are so many other things demanding attention that it is almost impossible to devote time to all, therefore some must be omitted or neglected. We know that the same number of varieties were not in cultivation years ago as there are at the present time, but whether they were hardier or not is an open question. We have now a long list of varieties all of which are said to be good, at least the descriptions given would lead those unacquainted with them to think so. There are, however, some of but little value, either as regards flavour or fruitfulness when grown against walls, more especially in cold districts, as they are too tender. The south of England is not altogether the most favoured part for the cultivation of peaches, though in some places they do fairly well. The great drawback here is the time they commence to grow in spring. Here some of the varieties were bursting into flower ere the shoots had been fastened to the walls. I noticed some of the blossoms showing colour as early as February 10, and no wonder that they receive a check later on when in full bloom. This is not only the case with the early varieties, but many of the late kinds are also showing flower. Some of what are termed first-class varieties are of no use whatever in this district.

Taking Barrington as an example, its fruit is large and of a good colour, but as regards flavour quite worthless, as it is both woolly and juiceless. Dr. Hogg is also only fit for stewing. The tree is also too tender for outside cultivation, as it is usually attacked with mildew in the most favourable seasons. Lord Palmerston is a pretty peach when well grown, and that is the only recommendation it possesses. Early Silver, though a fine peach under glass, is of no use on the open walls, and the same may be said of several of the newer kinds. Alexander does fairly well here, though in some seasons the foliage blisters terribly. Last season it was attacked in such a manner that very few leaves were to be seen until after midsummer. Bellegarde is a good peach; the tree is hardy and most prolific, nor is it so subject to mildew as some others. The fruit is of medium size, quite large enough for all ordinary purposes; the colour is good and flavour excellent. On the open walls we seldom fail to have a crop. Condor is also a good variety, producing fruits both large and of excellent flavour, but the tree is not very hardy. Grosse Mignonne is a good peach for outdoor cultivation; the tree is hardy and prolific, and the fruit both good in size and quality. Prince of Wales usually does well, and produces some fine fruit of most exquisite flavour. Royal George and Violette Hative both deserve a place on account of their fine flavour and productiveness. The best of the late varieties with me is Sea Eagle; this is both large and of good quality, and though not so hardy as some, usually produces a crop. Warburton's Admirable and Golden Eagle, in favourable seasons, are of fair quality and are the latest varieties we grow. Exquisite is of poor flavour here.

We defer pruning and nailing as long as possible to prevent the flowers from becoming too forward, and when the trees are finally fastened to the walls, netting is at once put over them to ward off the frosts, which with us are often very severe just as the trees are in bloom. The netting used is such as the fishermen have on the Cornish coast for catching pilchards, having a mesh of about half an inch. This, if hung loosely, will ward off several degrees of frost. It is, however, after the trees have gone out of flower that the most mischief is usually done, for if there should be cold east winds during May, the leaves blister to such an extent that most of them fall off, and the trees become so crippled that the summer is far advanced before a fair growth is made. If some protection can be afforded whereby the cold winds are warded off, the foliage will develop, and an early well-ripened growth will follow; but when a late, ill-matured shoot is made, this is so sappy as not to be capable of ripening, and the consequence is but few flower buds, and only one wood bud as the terminal. When trees reach this state it is seldom that they produce good fruit, and the best plan is to take them up to make room for others. Cold winds are not the only cause of failure. We are sometimes told that all growths should be laid in; that it is a mistake to take off laterals and so forth; that trees grown on the extended system, that is by laying in all the lateral growths that are made, give finer results. This, however, is a mistake, for such wood seldom ripens properly, and usually sets but few flower buds. Where there is a tendency in young trees to make over-luxuriant growths, the best plan is to stop them when three or four inches long, the sap will then be directed into other channels. The lateral growth from such shoots will not be so strong, but if by chance it should again take the lead, this may be stopped a second time when it has attained a length of eighteen inches. If one or two of the top buds from such shoots should afterwards break, these should be encouraged, as they will take the sap and so prevent the buds lower down from pushing. When trees are inclined to make too much wood it is a sign that the roots are too deep, as this seldom happens where the roots are near the surface. With young trees growing in borders that are highly fed for the production of good vegetables, there is some difficulty in keeping the roots shallow, as many of them then become injured in digging. It is, however, good practice to have the borders where peach trees are growing occupied with an early crop, which can be cleared off by autumn so that the roots may be lifted every second year and brought nearer to the surface. In the operation of lifting, the soil will be stirred to sufficient depth to allow the roots of vegetables to go down, and an abundance of young rootlets will be formed on the peach trees to maintain them in a healthy flourishing condition. Peaches in the open are often neglected when they require constant attention. That is soon after they have passed out of flower. Aphis then makes an attack on them, and if this is not kept in check soon causes the leaves to curl up and wither.

H. C. PRINSEP.

A FEW VINE NOTES.

THE exact time for vine planting will always be an open question, and in the majority of instances large growers have but little choice in the matter; the canes must be put in either as the houses are ready, or when the canes can be obtained. The spring, however, is the season when most are planted, and this on account of the tomato crop which is grown in the houses the first year or two. One thing I notice very particularly, and that is, as vines are planted and, of course, started, so do they expect to be made ready for starting in following seasons. Some vines under my own care were planted early in the first month of last year, the tomato plants being also ready; gentle fire heat was given at once, and the result now is that starting this set the second season at a similar date is no trouble at all. Again, vines planted in the autumn up to October take a good hold of the soil, and are of the best for early forcing. Late spring-planted canes, though generally doing well, have much to contend with, the chief drawback being the forwardness of the tops, which are far in advance of the roots, while the latter are not yet established in the new border.

With judicious culture year by year, a week or two can be gained if vines are required for any specially early crops, and the same in a degree applies to the late varieties. Thus, if a late house is well heated, it can well be started a fortnight later; for instance, a Gros Colmar house with four pipes has to have fire heat by March 1. A similar house with six rows can be started two or even three weeks later, and then catch up with the first. Such items are worth consideration, more particularly if the vines are established and fires have to be specially lighted for each house. Shutting up houses according to the weather, even during the resting period, will also be an aid to prompt starting. What all growers look for is a regular break, and also a strong one, as, given this, fruiting will be satisfactory. We have the advantage of inside borders, and the roots are thus not only at command, but also ready for work in fact, I begin to question if these roots are ever dormant, as I have particularly noticed after Christmas pruning there is a continuous bud swelling.

What is technically known as "vine breaking," or, in other words, bud bursting, is always a very anxious time for growers, more particularly with young vines and those started out of season. No doubt if we could always wait for a natural start, the vines would be both regular in this respect and also stronger, but against this would be the extreme lateness of colouring and ripening of grapes. I have made many little experiments this year to induce a regular break, and there is no doubt the more horizontal and nearer the ground and pipes the rods are the better the break. Not content with this, I have also reversed the rods more than once, and feel satisfied I have gained something. Rods tied down in the usual way will have a certain number of the buds on the under side; to reverse the rods and thus bring them to the front for a change must give both sides an equal chance of sun, &c. Of course, I am now dealing with young two-year canes. Older rods do break freely, and not only this, but also appear to start at the same time year by year.

Bottesford Nurseries, Notts. STEPHEN CASTLE, F.R.H.S.

NOTES FROM IRELAND.

FOR mild weather, accompanied with abundance of rain and wind, the winter of 1897-8 should break all records. Up till now we have had but one slight frost, and that early in autumn. I notice in several places geraniums that have been out in window-boxes all the winter are still in flower, and save where the foliage is damaged by wind, they are as fresh as in summer. Snowdrops were in full flower on January 1, and are now quite over, while they are succeeded by the crocuses and daffodils. I do not remember seeing the latter in flower during the second week in February before this season. Brompton and the intermediate stocks have been flowering continually throughout the winter, as also have wallflowers and polyanthus, with daisies, forget-me-nots, &c. Roadsides and hedgrows are gay with daisies and primroses; while the pleasure grounds have been ablaze with colour since early in November by reason of Rhododendron Nobleanum. We shall in all probability suffer for this mild weather during the present and following months; I have too frequently noticed after an exceptionally mild winter, we have sharp and frequent frosts in this locality at the time when fruit trees, &c., are coming into blossom.

The season of 1897 appears to have been a bad one for onions, as, save in one notable instance, everyone is complaining of the crop; to have the bulbs so small was bad enough, but that these should fail to keep is worse. The few apples and pears that came to perfection in this neighbourhood also kept very badly. Snow's Winter White, Early Penzance, and Adam's Early White broccoli are now rendering a good account of themselves; Penzance, I consider, is by far the best of this trio. I noticed a splendid plot of Ellam's Early spring cabbage at Summerville recently, from which, Mr. Ellicott had been cutting fine heads since January 15. As far as my knowledge goes, this is a record-breaker for early cabbage. The seed was sown about July 20, the resulting plants being afterwards planted in a large square in the open garden, and not on a sheltered border. After this, I am more firmly than ever convinced that Ellam's is difficult to beat as an early cabbage. In your issue of the 19th ult. "Lux" gives the opinion of his faithful henchman, the immortal "Peter," concerning seed potatos; well, last season I planted about half an acre of large Champions without cutting the sets in any way, the culture, otherwise, was as usual, but when the crop was lifted there was not any difference to be seen between them and the result from the smaller, or cut sets. After that test I am no longer an advocate of large seed potatos.

Glenstal. R. WELLER.

SNOWDROPS IN SHRUBBERRIES.

SNOWDROPS are so far accommodating that they may be successfully cultivated under diverse conditions without any special difficulty, as strikingly exemplified in many gardens of the United Kingdom early in the year. In some cases they may be found in irregular clumps along the margin of borders devoted to hardy perennials, in others they bespangle large areas of turf with "pendent flakes of vegetating snow," and occasionally they are employed with much success in carpeting borders occupied by deciduous shrubs. Under no conditions do they appear to greater advantage than when springing from the turf of orchards or pleasure grounds, as witness the charming effects annually produced in the grounds of Dunrobin Castle, and those of many others of our old country houses. But they do not invariably succeed when planted in the grass; and in many cases it is not easy to assign a cause for their gradually dying out, when in other gardens, where similar conditions appear to obtain, they grow vigorously, and produce an abundance of fully-developed flowers. There are, of course, many instances in which no difficulty is experienced in arriving at a correct conclusion in the matter, as, for example, when they are planted in positions where the mowing has to be commenced early in the year. In the case of snowdrops, as in that of other bulbous plants, a rapid decline in vigour, followed by death, is inevitable when the plants are deprived of their leaves before they have had time to complete their allotted functions. As so well understood by those who have a knowledge of plant physiology, the leaves are as essential to bulbous as to other plants, and without them the formation of the embryo buds and the storage of reserve materials required by the plant when commencing to make new growth are impossible, consequently, when planted in those parts of the lawn which have to be kept closely shaven from early in the spring until the autumn, they become so weakened by the removal of the leaves that they die out in a comparatively short period. In the mixed border they sometimes fail to give satisfactory results, owing either to their disturbance or to the soil being too rich to admit of the perfect maturation of the bulbs.

There is one position in the garden in which snowdrops invariably succeed, and that is the shrubbery border. Planted amongst deciduous shrubs the snowdrops enjoy sufficient light to enable them to complete their growth, and after the shrubs are clothed with leafage the roots absorb the moisture in the soil at so rapid a rate as to keep the border dry. Consequently the dryness of the soil checks the growth at a sufficiently early period to ensure the bulbs having a long season of rest, and by its continuance until the end of the summer it imposes a safeguard against premature growth. As the result of their being able to make their growth under conditions more favourable than in the mixed border or in the grass, and then having a full season of rest, snowdrops become thoroughly established in the shrubbery and give a wealth of flowers annually. In the Royal Gardens, Kew, they are employed with singular success in beautifying the shrubbery borders as so well shown in the accompanying illustration of a shrubbery planted with Galanthus Elwesi. At Kew they are planted rather thickly in borders devoted to philadelphus and other flowering shrubs, and the plants increase in number and vigour, and annually produce a delightful effect. The border illustrated is contiguous to the collection of British ferns, and each year proves immensely attractive to visitors during the period when the surface is carpeted with foliage and flowers. What has been accomplished at Kew may be repeated with more or less success elsewhere, and with a full knowledge of this we advise the general planting of the snowdrops amongst deciduous shrubs.

G.

ELWES' SNOWDROP (GALANTHUS ELWESI) IN SHRUBBERY AT KEW.

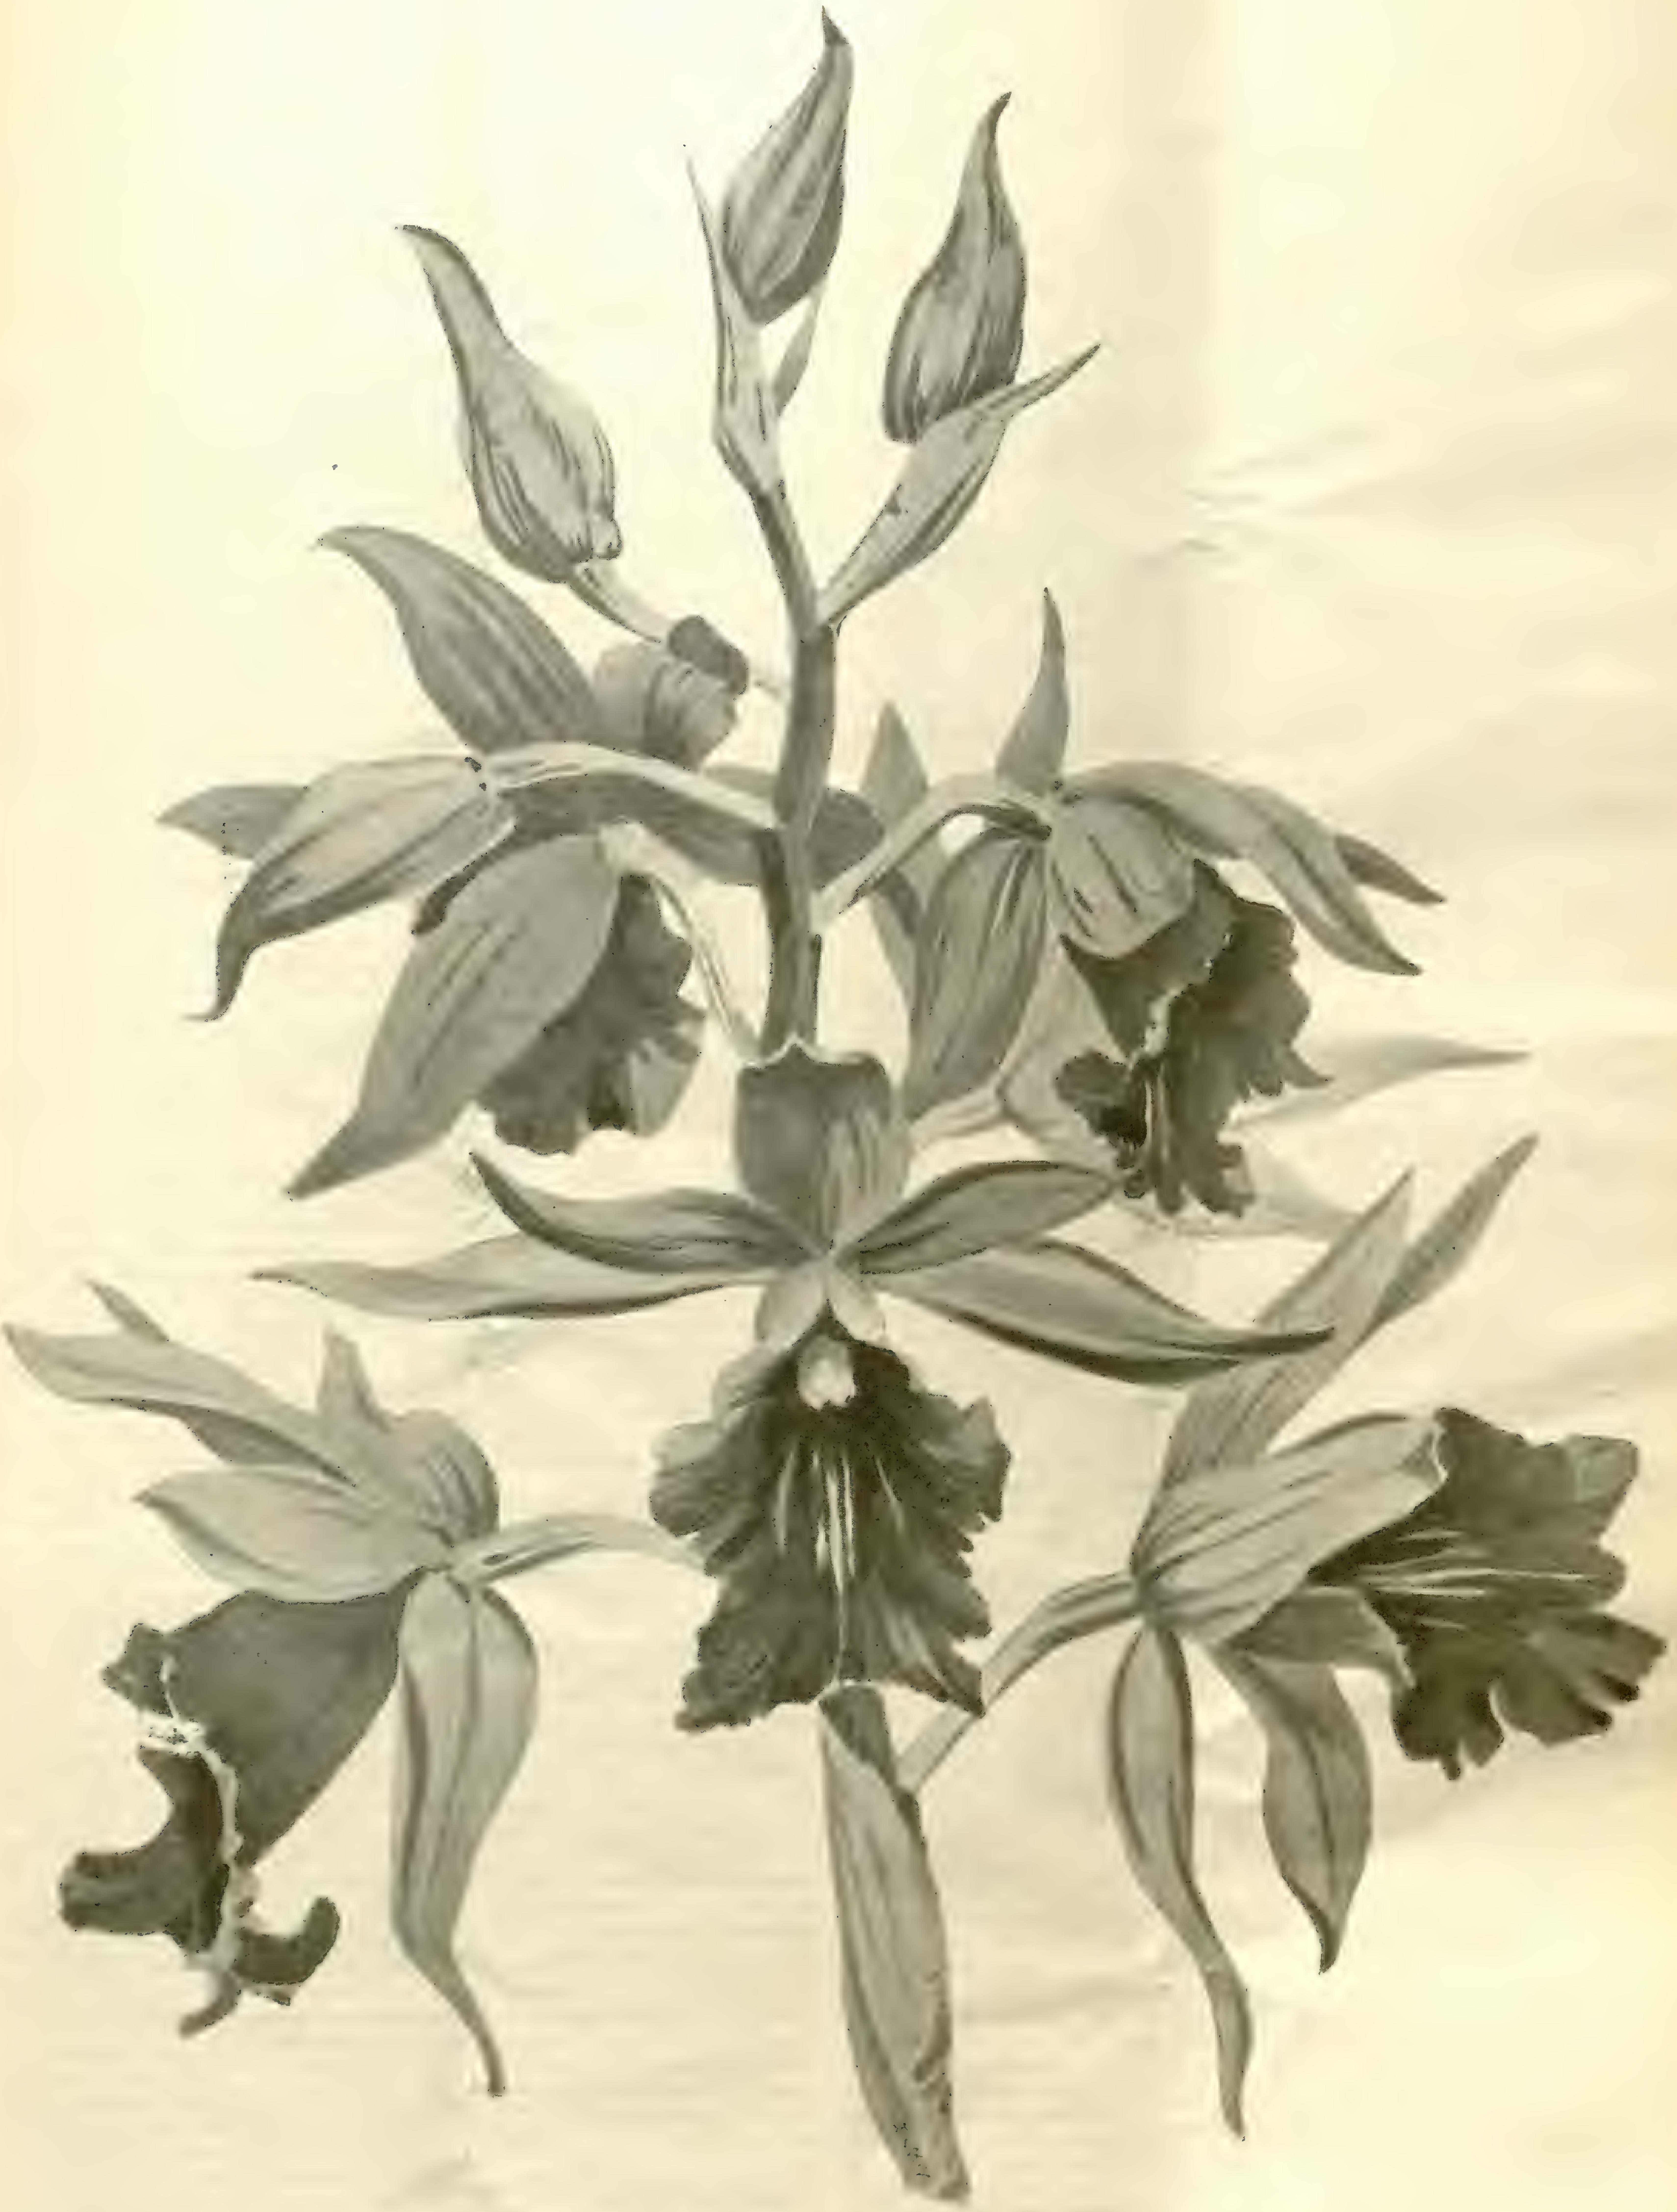
HYBRID PHAIUS.

THE numerous species and hybrids of phaius are not less remarkable for the beauty of their flowers than for their stately appearance. P. grandifolius, P. Blumei and its forms, P. Wallichi, and P. bicolor certainly combine the two attributes of beauty and stateliness, and the three former have to a large extent transmitted them to their progeny. The two most beautiful species, if we regard exquisite shape and colouring as the highest attributes of beauty, are those from Madagascar, viz., P. tuberculosus and P. Humbloti, neither of them being particularly easy to grow. These make up in beauty what they lack in size and stateliness. The first named of the two has been a great favourite with hybridists, as will be seen by a reference to parentage of hybrids given below. Phaius maculatus has been once used as a parent, and its merits, when well grown, should warrant its further utilisation for the production of garden phaius. It is extremely free-flowering, and if exhibited in bulk at some R.H.S. meeting it would not fail to attract attention. Some good specimens of this widely-distributed species are annually flowered in the cool orchid house at Kew. Those species of phaius which have not hitherto yielded hybrids, or, at, least, no hybrids from them have yet been flowered or recorded, are the Cingalese P. bicolor; P. philippinensis, from Mindanao and the Philippine Isands; and the comparatively new, and still rare, P. roseus, discovered by the Earl of Scarborough, and flowered in this country in 1892. Besides these there are several species that are hardly ever seen in cultivation, but which might prove of value to hybridists. For the purposes of this article Phaius Blumei will be considered as a distinct species, though it would seem most correct to give it as a variety of P. grandifolius, but Phaius grandifolius var. Blumei var. Sanderianus is too big a name for frequent repetition.

The honour of first seriously considering the advisability of producing hybrids of phaius belongs to Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, and his first effort was made with a view to combining the beauty of form and colour seen in P. tuberculosus, with the robustness of some more easily grown species, and P. Wallichi was chosen. The result was P. Cooksoni, named by Mr. R. A. Rolfe in honour of its raiser. It is now eleven years ago since Mr. Cookson commenced a series of experiments that have been wonderfully successful, for the majority of hybrid phaius are a tribute to his skill and foresight. Messrs. J. Veitch and Sons, Chelsea, and Messrs. F. Sander and Co., St. Albans, have also raised hybrid phaius of great value to horticulturists. The following is a descriptive list of phaius hybrids up to date, all bigeneric hybrids such as Phaio-calanthes, and those known in gardens as thunias which now constitute the deciduous section of the genus Phaius. being excluded.

P. AMABILIS was first brought into notice on February 14, 1893, by its raisers, Messrs. J. Veitch and Sons, Chelsea. This is a hybrid between P. grandifolius and P. tuberculosus. The flowers measure nearly four inches across, the sepals and petals being fully an inch and a half long, white, flushed with pink. The large lip has the side lobes clasping the column so as to form a tube which has a yellowish external base; the broad apex is rich purplish crimson with greenish veins towards the throat. The plant is intermediate between the two parents, and produces spikes about fifteen inches high. It was named by Mr. J. O'Brien, and has gained a F.C.C. from the Royal Horticultural Society.

PHAIUS COOKSONI is a robust hybrid between P. tuberculosus and P. Wallichi, the latter being the seed parent. In growth the plant is fairly intermediate in character between the parents, while in the flowers the pattern parent has transmitted its leading features to the labellum



PHAIUS NORMAN.

and left the sepals and petals to mostly resemble those of P. Wallichi. Naturally, when there are numerous seedlings from one cross, and also when in other establishments the same cross is effected between plants that differ slightly from the originals, there will be some diversity of colouring in the hybrids. This is so in P. Cooksoni, but as a general rule the sepals and petals are light rose, sometimes with a pale salmon hue or yellow brown tint along the middle; the petals are shorter than the sepals, and a trifle broader. The lip is funnel-shaped, and deep yellow on the lower basal portion externally; on the inner surface the colour is bright yellow at the base and along the disc; the sides of the throat are marbled with crimson brown. The mouth of the lip is broad, and the reflexing margin is beautifully frilled and crisped; this area is chiefly deep rose-coloured and spotted with rich carmine purple, each flower measures about five inches across, and ten to twelve are produced on a spike. Mr. Cookson effected the cross in February, 1887; the seed was sown in December of that year, and the seedlings flower when a little over two years of age. A first-class certificate was granted to this orchid by the R.H.S. on March 11, 1890.

PHAIUS COOKSONIÆ is another of Mr. Cookson's triumphs, and commemorates Mrs. Cookson. This is a fine orchid of the P. Marthæ class, and obtained by crossing P. Humbloti with P. grandifolius. The sepals and petals are nankeen yellow, tinted orange. The lip is a wonderful piece of work; side lobes scarlet veined with gold, front lobe deep rose streaked and mottled with crimson. There is a long yellow disk, and the margins of the front lobe are prettily frilled and crisped. P. Cooksoniæ was exhibited before the R.H.S. on June 11, 1895, and was awarded the prize as the best hybrid orchid of the year. The hybrid was figured in the GARDENERS' MAGAZINE of June 15, 1895, p. 353.

P. HYBRIDUS is the title given to an orchid obtained by Mr. Cookson by crossing P. grandifolius with P. Wallichi. The sepals and petals are coppery-yellow, and the lip is creamy. The flower much resembles that of P. grandifolius, except that the predominant colour is yellow and its shades.

P. HYBRIDUS GRAVESII is the result of the reverse cross to P. hybridus. It was also raised by Mr. Cookson, and flowered in the collection of Mr. H. Graves, Orange, New Jersey, and named in compliment to its owner by Mr. Rolfe. This has large flowers, and these resemble those of P. Wallichi; they are five inches across, and have cinnamon-brown sepals and petals with a whitish reverse; the lip is whitish, with a rosy front lobe and yellow keel.

P. MACULATO GRANDIFOLIUS is a Veitchian hybrid of singular beauty, and one whose parentage is recorded in its name. It has bold arching foliage, as in P. grandifolius; these are deep green, and make a fine contrast with the flowers. The latter are pale yellow tinged with rose, so far as the sepals and petals are concerned, but the lip is creamy white with a rich crimson-brown base and veinings of this colour on the front lobe. The side lobes are convolute, and the margins of the front lobe frilled in a charming manner. This hybrid gained the highest honour for a new plant from the R.H.S. on October 10, 1891.

PHAIUS MARTHÆ is a charming hybrid, and already a most popular phaius. It is one of Messrs. F. Sander and Co.'s hybrids, trained by crossing P. Blumei with P. tuberculosus. The sepals and petals are pale buff yellow and of good size and substance. The lip is also pale yellow with a large golden disc; the lateral areas of the apical lobe are a pretty shade of rosy crimson. Awarded a first-class certificate, R.H.S., on March 13, 1894. In growth P. Marthæ is intermediate between its parents, but it has a fine constitution and flowers freely.

P. NORMAN was described in the issue of March 12, and is figured in the present number. It is a wonderfully beautiful and effective hybrid between P. Blumei Sanderianus and P. tuberculosus. The flowers are large and the sepals and petals are coloured with carmine and rose, while the large and handsome lip has old gold or orange side lobes, and a large spreading apex that has a rose foundation and mottlings of red and crimson. The long disc or keel is golden. *P. Norman rosea* is from the same seed-pod as the former, and is wonderfully free, quite small plants carrying three spikes. The flowers are scarcely so large as in the type, and differ in having rosy sepals and petals, a more yellow throat to the lip, and a more crimson front lobe. *P. Norman aurea* is very distinct, though also from the same seed-pod. It has large pale yellow sepals and petals, and a yellow base to the lip. All three are very fine orchids, and the two former gained each an F.C.C. and the latter an A.M. from the R.H.S. on March 8 last. The cross was effected and the plants raised by Mr. N. C. Cookson, and the whole stock of seedlings was purchased from him by Messrs. Charlesworth and Co., Heaton, Bradford. This firm exhibited those forms already described, and they hope to have further variations, as several seedlings are as yet unflowered. The first plant flowered at four years of age. Phaius Norman and its forms grow well in an intermediate house, and are remarkable for their robustness and freedom of flowering. When in bloom they can be taken without fear of harm to a conservatory, where the flowers will last for six weeks in perfection. P. tuberculosus was the pollen parent in this case as in most others.

P. OWENIANUS is a handsome phaius raised by Messrs. F. Sander and Co., St. Albans, and exhibited by them at the R.H.S. meeting of May 23, 1894, when it gained a F.C.C. This form has for its parents P. Humbloti and P. Oweniæ, the latter being the pollen parent. It is a fine hybrid, with purple-brown or crimson-brown sepals and petals, and a lip that is a delightful combination of gold, crimson, and magenta; the triple keel is golden, but the prevailing colour of the lip is crimson. This hybrid was two years and ten months old from seed sowing when it flowered.

P. OWENIÆ came from the St. Albans Nursery, but the parentage does not appear to have been recorded. It somewhat resembles P. bicolor, but has brownish purple sepals and petals. The lip has a chrome yellow base, and a rich bright purple front lobe tinged with crimson. When shown by Messrs. F. Sander and Co. on April 24, 1894, an award of merit was granted.

C. H. C

WORK FOR THE WEEK.

COOL ORCHIDS.

THE usual time for repotting Odontoglossum crispum is the early autumn, but any plants that have passed out of flower, and are in sour material, must quickly be removed from such, or else the new roots will be killed as fast as they are put forth. Pots large enough for the development of the next two years' growth should be used, with plenty of drainage, and the plants should have all the old material removed from their roots, and any old roots cut away. Repot in a compost of good fibrous peat and sphagnum moss, and place in the shadiest position, and frequently damp between the pots to keep a moist atmosphere. Care must be taken in watering, allowing the compost to become moderately dry before giving water. Semi-established plants should have a little of the old material carefully picked out and be resurfaced with fresh, clean moss. Odontoglossum madrense should be repotted or top-dressed, as necessary, while O. Harryanum, also O. nebulosum, will also require a little new material at this season. O. Andersonianum, in variety, is now making a nice show of branched spikes, and produces a good effect arranged with the O. crispums; the spikes last for a long period in perfection, but this naturally weakens the plants, and is likely to have unsatisfactory results. The flower-spikes, after they have been open a reasonable length of time, should be cut off and placed in water, where they will remain fresh for a further period. The culture of O. Andersonianum does not differ materially from that of O. crispum, but it is perhaps a rather better grower. Dendrobium infundibulum is now in bloom, and its beautiful pure-white sepals and petals, and golden-blotched lip, form flowers that last five to six weeks in perfection, and are most useful for cutting. This species greatly resembles D. formosum, but has more slender stems. There are but few dendrobiums which can be cultivated with much success under cool treatment, but this species, like D. Jamesianum, thrives admirably in the odontoglossum house, suspended from the roof, and does best in pans or baskets of small size, allowing sufficient water to keep the compost nicely moist during growth, and in winter enough to prevent shrivelling of the pseudo-bulbs.

Lælia præstans is a species that is often grown in an intermediate temperature, but it may be grown with equally good results in company with the odontoglossums, and undoubtedly the flowers that are produced in the autumn are much better in colour than those seen in a warm house; it is a dwarf grower, and should be grown in pans or baskets, suspended from the roof, at the warmest end of the house, but as near the glass as possible, and where there is plenty of light. These plants may now be repotted or top-dressed as each particular case demands; the usual compost of peat and sphagnum will suffice over good drainage. Keep this nicely moist, and never allow it to become dry while the plant is growing. The same remarks apply to Lælia Dayana and L. pumila. Any plants of Epidendrum vitellinum that require repotting or top-dressing should be attended to at once; pots are preferable to pans or baskets for their culture, but in any case a light position in the cool house is essential; do not allow them to become dry at this season, or the flower spikes, which will soon commence to show, may be weakened. Cypripedium villosum and C. Boxalli that have finished flowering ought to be repotted at once, if this is necessary, using compost as advised for C. insigne in a former calendar. Continue the same care in ventilating as previously advised, and damping down two or three times a day in bright weather.—E. SHILL, *New Hall Hey Gardens.*

STOVE PLANTS.

THE sun has now so much power that shading will be necessary during the middle part of the day for the majority of the occupants of the stove. Where blinds are available they should now be fixed in position, to be lowered on all bright days about half-past ten and drawn up again about two p.m., at the same time giving the house a thorough syringing. Where blinds are not available and where permanent shading is resorted to in the way of Summer Cloud to protect the plants from the strong rays of the sun, something temporary should be arranged for a few weeks as it is too early at present to apply the permanent shade; mats thrown over the roof, loose pices of tiffany, or, failing these, a light wash of whitening and water will afford a protection from the sun. If a house can be given up to crotons altogether these will require no shading whatever after they become established in their new pots, affording them plenty of heat and atmospheric moisture, as it is only under such treatment that their brilliant colouring is seen to perfection. Marantas are generally impatient of strong sun, and should be arranged in the most shady part of the house; dracænas should be kept toward the shady end. When all the repotting is done have the gravel, or whatever material the plants stand upon, turned or renewed, and arrange the plants so as to allow each the maximum of space, and instead of arranging on the dot system try the effect of massing. Old plants of strobilanthus that were cut down a few weeks ago are producing plenty of cuttings now; insert these singly in thumb pots containing equal parts of loam and leafsoil with sand added; if plunged in the propagating case, kept shaded and attended to for water with an occasional syringe overhead, they will be rooted in a fortnight, when they can be stood in the body of the house for a few days before potting on.

The earliest tubers of caladiums will be now ready for potting on, and a suitable compost for their successful culture consists of equal parts of turfy loam, fibrous peat, and leafsoil (the two former not pulled or broken down too fine), a little well-decayed manure, with a good sprinkling of sharp silver sand. When potting, a little discretion is necessary to place the weak growers in smaller pots, and the stronger growers into larger ones. Afford good drainage, as caladiums need a quantity of water during the growing season; press the compost firmly with the fingers. The varieties of caladium have increased wonderfully of late years, and no collection can be complete without it contains a few, at least, of the newer kinds. A few that will be found useful are Candidissima, Prince of Wales, Comtesse de Condeixa, Reine de Portugal, John R. Box, Luddemanni, F. W. Moore, Her Majesty, La Lorraine, Alice Van Geert, Botafogo, and Princess Royal. After potting they will be benefited if plunged in a moderate bottom heat for a time, as this will stimulate root action, and reduce the necessity of watering to a minimum until the soil is occupied with roots. Cuttings of Adhatoda vasica and A. cydoniæfolia may now be inserted; they strike readily in bottom heat, and the latter is a useful subject for training up pillars in the stove; the flowers are white and purple, and make a splended display towards the end of the summer. If grown in pots, pinch frequently in the early stages of growth, or it will present a straggling appearance. Adiantum Farleyense will now be pushing into growth, and any repotting or splitting up necessary should be attended to; this adiantum thrives better without peat; a compost of two parts loam, one part leafsoil, and a good sprinkling of sharp sand, also a few pieces of broken sandstone, and a little of some good artificial manure will suit it admirably; afford a light position at the coolest end of the stove, do not shade too heavily, and do not syringe them overhead. During mild weather the night temperature of the stove should be 65 to 70 degrees, by day 70 to 75 degrees, allowing a fall of five degrees on cold days and nights; this will be found better for the plants than trying to keep up to the maximum temperature by means of excessive heat in the pipes.—J. Tunnington, *Ripley Castle Gardens.*

KITCHEN GARDEN.

In the southern counties and in warm situations it will be necessary to commence putting out plants that have been protected in frames through the winter or have been raised under glass. Cauliflowers should be the first to command attention, as most of the plants raised from seed sown in the autumn have grown large; great care must be exercised in transferring them to the open quarters, removing them with balls of earth attached if possible, for should they flag to any considerable extent in all probability bolting will take place. If potted as previously advised they may be planted out without any fear of their suffering through disturbance, but when planted from the open frame protection of some kind must be afforded until the roots are running in the soil. Should the weather be showery at the time of planting, this may be dispensed with, but if the sun is bright in the daytime an inverted flower-pot put over each plant will materially check evaporation. Plants raised from seed sown in January should be thoroughly hardened off before being planted out, otherwise they will suffer considerably. Lettuces that have been afforded the protection of a cold frame, and those that were pricked out on the open borders in the autumn should now be planted out, while plants raised from seed that was sown in heat should be hardened off that they may be ready whenever a favourable opportunity occurs for planting. Where new plantations of Globe Artichokes have to be made, the present is a favourable time to perform the work. In all private establishments a portion of the stock should be taken up and replanted each year. This will not only keep the plants in a healthy condition, but will prolong the season of this useful vegetable. The present winter has been favourable to this vegetable, the young growths being well advanced at the present time. Those springing from the old stems near the surface should be discarded, as these seldom produce fine fleshy heads; rather choose those that start the lowest, as such will grow away more freely and send up stronger flower stalks. If these are planted in rows three feet apart and kept well watered until roots are formed, the plants will then take care of themselves. A dwarf crop of some kind may be taken from between the rows, such as turnips or lettuce. Artichokes like good ground, in fact it cannot be well too rich; and for this reason, when it is of a questionable character, give a good top-dressing of thoroughly decayed manure.

Jerusalem artichokes may now be planted, choosing medium-sized sets, and planting them in an open place. Often the crop of these is unsatisfactory, as they are planted too much in the shade, and not allowing sufficient room. Though artichokes will grow almost anywhere, far better results will be obtained if a sunny spot is chosen for them, and a distance of two feet six inches or three feet allowed between the rows, and half that distance between the sets. Horse radish is also another neglected vegetable, being often put out in any out-of-the-way place, instead of cultivated in rows properly. The whole of the old bed should be taken up, selecting those roots that are large enough for use, and laying them in by themselves. Those about the thickness of a man's finger ought to be selected for sets, and after rubbing off all the small rootlets, plant in rows two feet apart, allowing a distance of nine inches between the plants. The ground for this crop cannot be too rich, therefore, previous to planting, it should be liberally manured and deeply trenched. Those who have not yet planted their seakale sets should lose no time in doing so; for, though they will not start into growth until the soil is warmer, roots will commence to form, and growth will be more rapid later on. There is much art in getting large well-matured crowns for early forcing, particularly on poor ground, and unless a good start is made, there is not time for growth to mature. Asparagus beds ought to have the surface slightly loosened, that the sun's rays may the more readily warm the soil and encourage the growths. Whenever the soil is sufficiently dry on the surface, run the hoe through all growing crops, such as spinach, cabbage, parsley, onions, &c. If these are afterwards dressed with artificial manure, they will grow away far more rapidly. Attend to sowing small seeds, such as spinach, lettuce, radishes, brussels sprouts, cauliflower, carrots, and parsnips, whenever the weather is favourable.—H. C. Prinsep, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

Peach trees in all stages of growth will require considerable attention as to the manipulation of both wood and fruits, early trees having had the fruits thinned and shoots disbudded down to the number requisite for a crop, and growths laid in to furnish a supply of bearing wood for next year. The latter will require tying in carefully, so that it may be evenly distributed over the trees and in a proper direction to preserve the general trend of the branches outward. Misplaced growths which have been left on to draw sap to any fruits left at their bases should be kept rigorously pinched in. Personally, I rarely find it necessary, except in the case of very shy bearing varieties, to preserve any of such shoots. As regards thinning the fruits, past experience will be the best guide as to whether they may be safely reduced to the number needed for a crop, before stoning, or whether a certain percentage must be allowed for dropping during that process; in some gardens no such reserve is necessary, while in others it would be unwise not to leave it. During stoning there should be no raising of the temperature, this being the best means of counteracting any tendency to dropping; 55 degrees as a maximum night temperature may be considered safe. See that the roots are kept sufficiently moist, and that the trees are syringed freely when the weather is favourable, this being the best means of keeping down red spider. Mid-season trees should have the surplus shoots removed by degrees until disbudding is finished, but I do not recommend great hurry in this work, but prefer to spread the work over several weeks. The main point to bear in mind when disbudding peach trees is to carefully reserve a well-placed shoot near the base of last year's growth and another near the end of such growth, though it may be necessary for fully furnishing the trees to allow also a few intermediate shoots to form, but no shoots should be retained eventually without a definite reason for their retention, as crowding the trees with surplus growths is very bad management, resulting in weak and badly ripened wood. Trees in cold houses will now be in bloom, or just passing out of that stage, and with these the work of thinning may be begun at once, and soon brought to a close, first of all removing all embryo fruits from the under sides of the shoots, and then those worst placed on the upper portions, keeping an eye to having the crop evenly distributed over the trees, at about one foot apart. During the bitter east winds prevalent in March it is no uncommon thing to find, in these cold and oftimes draughty houses, that an attack of mildew has set in almost before the trees have begun to grow, and this necessitates a close watch being kept on the tiny shoots of such varieties as Royal George and Red Magdalen, which are peculiarly liable to mildew, and an application of flowers of sulphur made to all shoots affected; early attention to this will prevent bad attacks.

Where it is intended to inarch new sorts of grapes on old stocks, it is best to have the new ones in the form of strong canes in pots; these should be brought into the vinery and stood in position a week or two after the house is started, as it is well to have the stock in a slightly advanced stage of growth to that of the scion. Place the pot in such a position that the shoot selected can be easily brought into connexion with a well-placed shoot on the stock, and when the growth of both has advanced to a semi-hardened condition, take a corresponding slice off the sides of either, taking care not to cut too deeply; then bring the two cut surfaces together, and bind tightly with raffia. In about a month the stock shoot may be cut back to within three or four leaves of the junction, and from that time all the force will go to perfect the growth of the scion, so that it is possible to grow quite a strong cane the first year. Where pot vines can be spared for the work it will be found that inarching is far superior to grafting for vines. Forward pine suckers may now be removed by twisting them out at the point of union with the parent stem, and after having a few of the smallest leaves stripped off, a small portion of the stem should be removed, when the sucker will be ready for potting up.—J. C. Tallack, *Livermere Park Gardens.*

THE STRUGGLE OF PLANTS FOR EXISTENCE.

In an able lecture given at the Ipswich Museum on the above subject, Mr. W. E. Watkins, secretary of the Technical Education Committee, stated that food was the first necessity of all living things, animal or vegetable, and the means employed in obtaining that food gave rise to the greater part of the variety of life, or the struggle for existence. Taking a twig of pine and burning it they would find that the residue was a fine ash, which was all that remained of what the tree had obtained from the soil. The rest of the wood had disappeared in smoke and gas into the air. It was from the air that plants derived most of their food, taking it in by the stomas, or leaf mouths; after entrance the air circulated through a great number of little cells, each of which was a microscopic chemical laboratory, where the plant manufactured from the air its sugar, gum, starch, and cellulose. It was the carbonic acid gas in the air that the plant utilised, and of this ingredient there were only four parts in every ten thousand. Yet out of that their great forests and fruitful cornfields were formed. During sunlight each of the little plant cells was actively at work, using up the carbon, and allowing the oxygen to return to the air. So while the plant was absorbing a gas that was very harmful to animal life, it was giving back oxygen for animal consumption. The lecturer demonstrated by experiment the process of absorption and manufacture alluded to, showing the immense importance of air space for plants, and the necessity of avoiding crowding, or weed aggression, that both rob the soil and air at the expense of the plant in cultivation. So true was this that at Bramford crops of wheat and barley had been grown for five years successively on unmanured land, and had produced larger crops than elsewhere in the neighbourhood by simply keeping the land clean and free from weeds, and enabling the plant to have a chance of getting the cheapest of all foods—air.

Mr. Watkins then turning to the fungi and bacteria, said that the mushroom and the mould on jams were both true plants; so also were bacteria. They were totally unlike the green flowering plants, which were homely in their tastes, and were content with water, air, and soil. The fungi and bacteria required highly organised food stuffs. They fed upon the gums, sugar, &c., of the green plants, and some particularly fastidious required even the blood of man for their sustenance. Throwing a succession of examples on the screen, their characteristics and habitat were discussed. The cholera and anthrax bacteria were among the most interesting. These plants were inconceivably small, and yet their work for good or evil was inestimable. It had been observed that a single bacterium would split itself into two bacteria in twenty minutes, and, if in a suitable medium, in eight hours they would become upwards of sixteen millions. Each microbe worked upon the blood as a ferment, splitting up the chemical components round it to make food for itself. In its struggle for existence it attacked the life blood of the animal, and the functions of the organs were disturbed. But there were other bacteria that were useful to man, such, for example, as the microbe that curdled the milk and enabled them to make cheese, and the fungi utilised for the preparation of a green cheese. There was a generally prevalent idea that in some cheeses the green streaks were caused by the use of copper wire. This was not so; the copper wire was used to make holes through the cheese, and the air introduced the pencillium microbe that at once began to grow. It was precisely the same kind of microbe as attached itself to damp boots, and the reason for the mould on boots was because the blacking employed contained sugar. The white fungus sometimes found on cheese was dung fungus, and indicated that the producers of the cheese were not sufficiently clean and careful in their dairy work. Very much allied to the bacteria were the yeast plants, which had been used so long by man to produce a leavened loaf. These plants required oxygen, and to obtain it they split up the sugar, and converted it into carbonic acid gas and alcohol. The gas escaped from the vat, the alcohol mixed with the wort and converted it into beer.

Turning to parasitic plants, a variety were thrown upon the screen showing how insidiously they worked and sapped the life of the plants to which they attached themselves. Among these he enumerated the familiar "witches broom" on cherry trees. The vine fungus and the means to combat it were also dealt with, and a most interesting lecture concluded with some curious lantern slides exhibiting the action of certain fungi, carnivorous plants, &c.

Pruning Newly-planted Fruit Trees.—Every year the question crops up, Should newly-planted fruit trees be hard pruned or not? This inquiry probably arises from the fact that fresh people are constantly taking to fruit culture, and hardly know which course is the best to take. When at the Cobham vineries, to which I recently referred, the manager said, "No matter how strong the rods of the newly-planted vines, I cut them hard back to the ground line, and let them make entirely new rods." The result is strong root action also, so that the roots and wood react upon each other to each other's best production. Precisely the same thing occurs in newly-planted trees. If wanted to bear fruit immediately, without consideration for their future welfare, then leave the wood growths alone after planting. Very poor root action corresponds with poor wood growth, and the buds generally are converted into fruit buds, which the following year carry bloom, though much of it may be infertile; but generally a crop results, and the tree in consequence receives a check from which it is long recovering. Especially in the case of standard trees, but the application is general, it being wisest to cut back, say to one third their length, the heads as received from the nursery. Thus the new branches are fairly stout and well leaved, creating strong sap action, which aids strong root action also. It is of the highest importance to secure strong growth both top and bottom at first, even if, a few years later, lifting or rod pruning be needful to check wood development. The wood must be first secured in any case, and if later found to be too luxuriant, root check will soon bring fruitfulness. Into the culture of fruit trees for any purposes, much that seems to be artificial treatment must inevitably be applied; but whilst Nature's chief aim seems to be the production of wood, the cultivator wants a crop of fruit also.—A. D.

LAW.

ARE GLASSHOUSES AGRICULTURAL LAND?

THE question whether glasshouses in nurseries and market gardens may for rating purposes be regarded as agricultural land has during the past twelve months been much discussed, both in horticultural and legal circles, and may now be considered to have been fully answered. On the 11th inst., judgment was given in the Court of Appeal on an appeal (SMITH and OTHERS, Overseers of Worthing v. RICHMOND, Surveyor of Taxes), argued before the Master of the Rolls, Lord Justice Rigby, and Lord Justice Vaughan Williams, by the surveyor of taxes from a decision of the Divisional Court given on August 2, 1897.

The question came before the Divisional Court on a special case stated by the quarter sessions for West Sussex on an appeal by the overseers of the parish of Worthing from a decision of the assessment committee of the union of East Preston under the Agricultural Rates Act, 1896 (59 and 60 Vict., c. 16). The case raised an important point relating to the rating of glasshouses in market gardens. By section 1 of the Agricultural Rates Act, 1896, "the occupier of agricultural land" in England is made liable, in the case of every rate to which the Act applies, to pay one-half only of the rate in the pound payable in respect of buildings or other hereditaments. The facts, as summarised in the *Times*, were as follows: Robert Piper was a grower of fruit, vegetables, and flowers at Worthing, and described himself and was commonly known as a market gardener and nurseryman. He was the owner and occupier of rather more than four acres of land, on which fifty-seven glasshouses or greenhouses of various sizes were erected. The houses were used by the appellant for the purpose of growing tomatos, cucumbers, and grapes, and, to a smaller extent, other vegetables, for the purpose of sale. The plants and crops grown therein were watered and heated by artificial means, and grown upon soil placed upon prepared beds inside the houses and matured much earlier than in the open ground. The vines were planted inside the houses and the roots ran partly in the soil under the houses and partly passed through apertures in the walls into the soil outside. Fifty-one of the glasshouses were thus used for growing vines. In the cucumber houses (which were six out of the fifty-seven houses) there were inside the houses dwarf brick walls supporting corrugated iron sheets, upon which soil taken from the other parts of the nursery ground was placed. In the beds so formed the cucumber plants were planted. Beneath the iron sheets and between them and the ground there were hot-water pipes. The area actually occupied by the fifty-seven houses was rather more than two acres. The rest (rather more than two acres) consisted chiefly of vine borders, paths, and the stokeholes. The whole of the houses were built upon dwarf brick walls like an ordinary greenhouse. It is provided by section 9 of the Act that, "unless the context otherwise requires, the expression 'agricultural land' means any land used as arable, meadow, or pasture ground only, cottage gardens exceeding one quarter of an acre, market gardens, nursery grounds, orchards, or allotments, but does not include land occupied together with a house as a park, gardens other than as aforesaid, pleasure grounds, or any land kept or preserved mainly or exclusively for purposes of sport or recreation, or land used as a racecourse."

For the purposes of the Act section 6, subsection 1, requires certain returns to be made to the Local Government Board. Subsection 2 provides that "for the purpose of the returns statements showing the gross estimated rental and rateable value of the agricultural land in a parish, and in the case of any hereditament separately valued which consists in part of agricultural land and in part of buildings or other hereditaments of each such part, shall be made by the overseers of every parish and corrected by the assessment committee and sent to the surveyor of taxes and be subject to objection or appeal by the said surveyor and overseers" as therein provided. In pursuance of the requirements of subsections 1 and 2 of section 6, of certain regulations made by the Local Government Board under subsection 3 of that section, the overseers made the prescribed statements, and sent them to the assessment committee and the surveyor of taxes, and in such statements they returned Mr. Piper's property and other property of a similar nature as agricultural land. The assessment committee, however, on the objection of the surveyor of taxes, decided that the statement, to the extent to which it includes land partly covered with glasshouses, was incorrect, and corrected it by striking out that entry. Upon the hearing of the appeal before the quarter sessions it was contended for the appellants, the overseers, that the particulars of the gross estimated rental and the rateable value of the hereditaments in question were correctly entered by them in their statement under the heading of "agricultural land," and that the decision of the assessment committee to correct the statement by striking out the entry was wrong, and in support of their contention they cited the case of "Purser v. Local Board for Worthing" (18 Q.B.D., 818). For the respondent it was contended that the case relied on by the appellants did not decide that glasshouses were not buildings, but merely that the land was not the less used as a market garden because the glasshouses had been placed upon it, and that the definition of agricultural land in the Agricultural Rates Act, 1896, was to be read subject to the context, and that the context in the Act required that any buildings should be excluded from the term agricultural land, that the glasshouses were buildings within the meaning of the Act, and that it followed that either the whole of the hereditament in question should be excluded from the overseers' statement, or, alternatively, that so much thereof as consisted of buildings should be inserted under the heading of "buildings not being agricultural land." The quarter sessions were of opinion that the contention of the appellants was right, and allowed the appeal and ordered the statement of the overseers to be altered by restoring all the items which formed the subject of the appeal to the condition in which they were before they were altered by the assessment committee, subject to the statement of a case for the opinion of the Court. Upon the appeal to the Divisonal Court the Judges differed, Lord Justice Collins being of opinion that the buildings in question were to be treated as part of the market garden, while Mr. Justice Ridley thought that no buildings were entitled to the partial relief granted to agricultural land. Mr. Justice Ridley, however, as junior Judge, withdrew his judgment, and consequently the appeal was dismissed. The surveyor of taxes appealed to the Appeal Court. The appeal was heard on February 8.

The Attorney-General (Sir Richard Webster, Q.C.), Mr. Day, and Mr. Trevor appeared in support of the appeal; Mr. Joseph Walton, Q.C., and Mr. Clavell Salter were for the overseers.

The Master of the Rolls said,—The question in this case is whether glasshouses in or on a market garden are to be rated as buildings or as agricultural land under the Agricultural Rates Acts, 1896. The Court of Quarter Sessions held that glasshouses ought to be rated as agricultural land. On appeal to the Queen's Bench Division the members of the Court were equally divided, and the appeal was dismissed, but leave was given to appeal to this Court. The glasshouses in question are clearly buildings in the ordinary legal meaning of the word. The case stated leaves no doubt on this point. The question turns entirely on the true construction of the Act of Parliament, 59 and 60 Vict., c. 16. The ninth section contains a definition of agricultural land, but no definition of buildings nor of market gardens or nursery grounds. The Interpretation Act, 1889, contains, in section three, a definition of land; and, this word, when used in subsequent statutes, is to include buildings, unless a contrary intention appears. The Interpretation Act, 1889, contains no definition of buildings, market gardens, or nurseries. The ninth section of the Act of 1896 clearly shows that land there cannot possibly mean or include buildings in the early part of the section, for the definition is that agricultural land means any land used as arable, meadow, or pasture ground only. Market gardens and nursery grounds are, however, also declared to be agricultural land, and this is the enactment which gives rise to the difficulty with which we have to deal. The definition in section 9, however, must not be used to contradict other parts of the Act, or to introduce anomalies which the language of the enacting part of the statute does not justify. Market gardens and nursery grounds may or may not have buildings upon them. If they have not no difficulty arises; but if they have, then comes the question, how are those buildings to be rated? To answer this question, we must look to the enacting clause, which is section 1. Here we have "agricultural land" used in connexion with, and, as I think, plainly contrasted with, "buildings and other hereditaments." Similar language is used in sections 5 and 6. This express mention of buildings makes the whole statute perfectly clear to my mind, and removes the doubt caused by the use of the words "market gardens and nursery grounds" in section 9. The only conclusion at which I can arrive is that buildings are not to be treated as agricultural land for rating purposes under the Act of Parliament. The case of "Purser v. Worthing" (18 Q.B.D., 818) does not, in my opinion, assist the Court in construing this Act of Parliament. That case merely shows that a market garden *prima facie* includes the buildings upon it used for market garden purposes. To urge that market gardens and nursery grounds do not cease to be so because they are more or less covered with glass houses is to urge what is quite true, but is beside the mark. The question is, how are such houses to be rated under this Act of Parliament? My answer is, if they are buildings, they must be rated as such, and not as agricultural land. Mr. Salter, in his very able argument, suggested that buildings used only for covering land which was cultivated under their protection ought to be distinguished from other buildings, and ought to be held to be agricultural land. I can find nothing to justify a distinction between one class of buildings and another for any such purpose as his argument requires. Section 5 speaks, no doubt, of buildings used for the cultivation of land, but this clause in no way shows that such buildings or any others are to be rated as agricultural land. In my opinion, the appeal must be allowed and the orders of the Queen's Bench Division and of the quarter sessions must be reversed, with costs here and below.

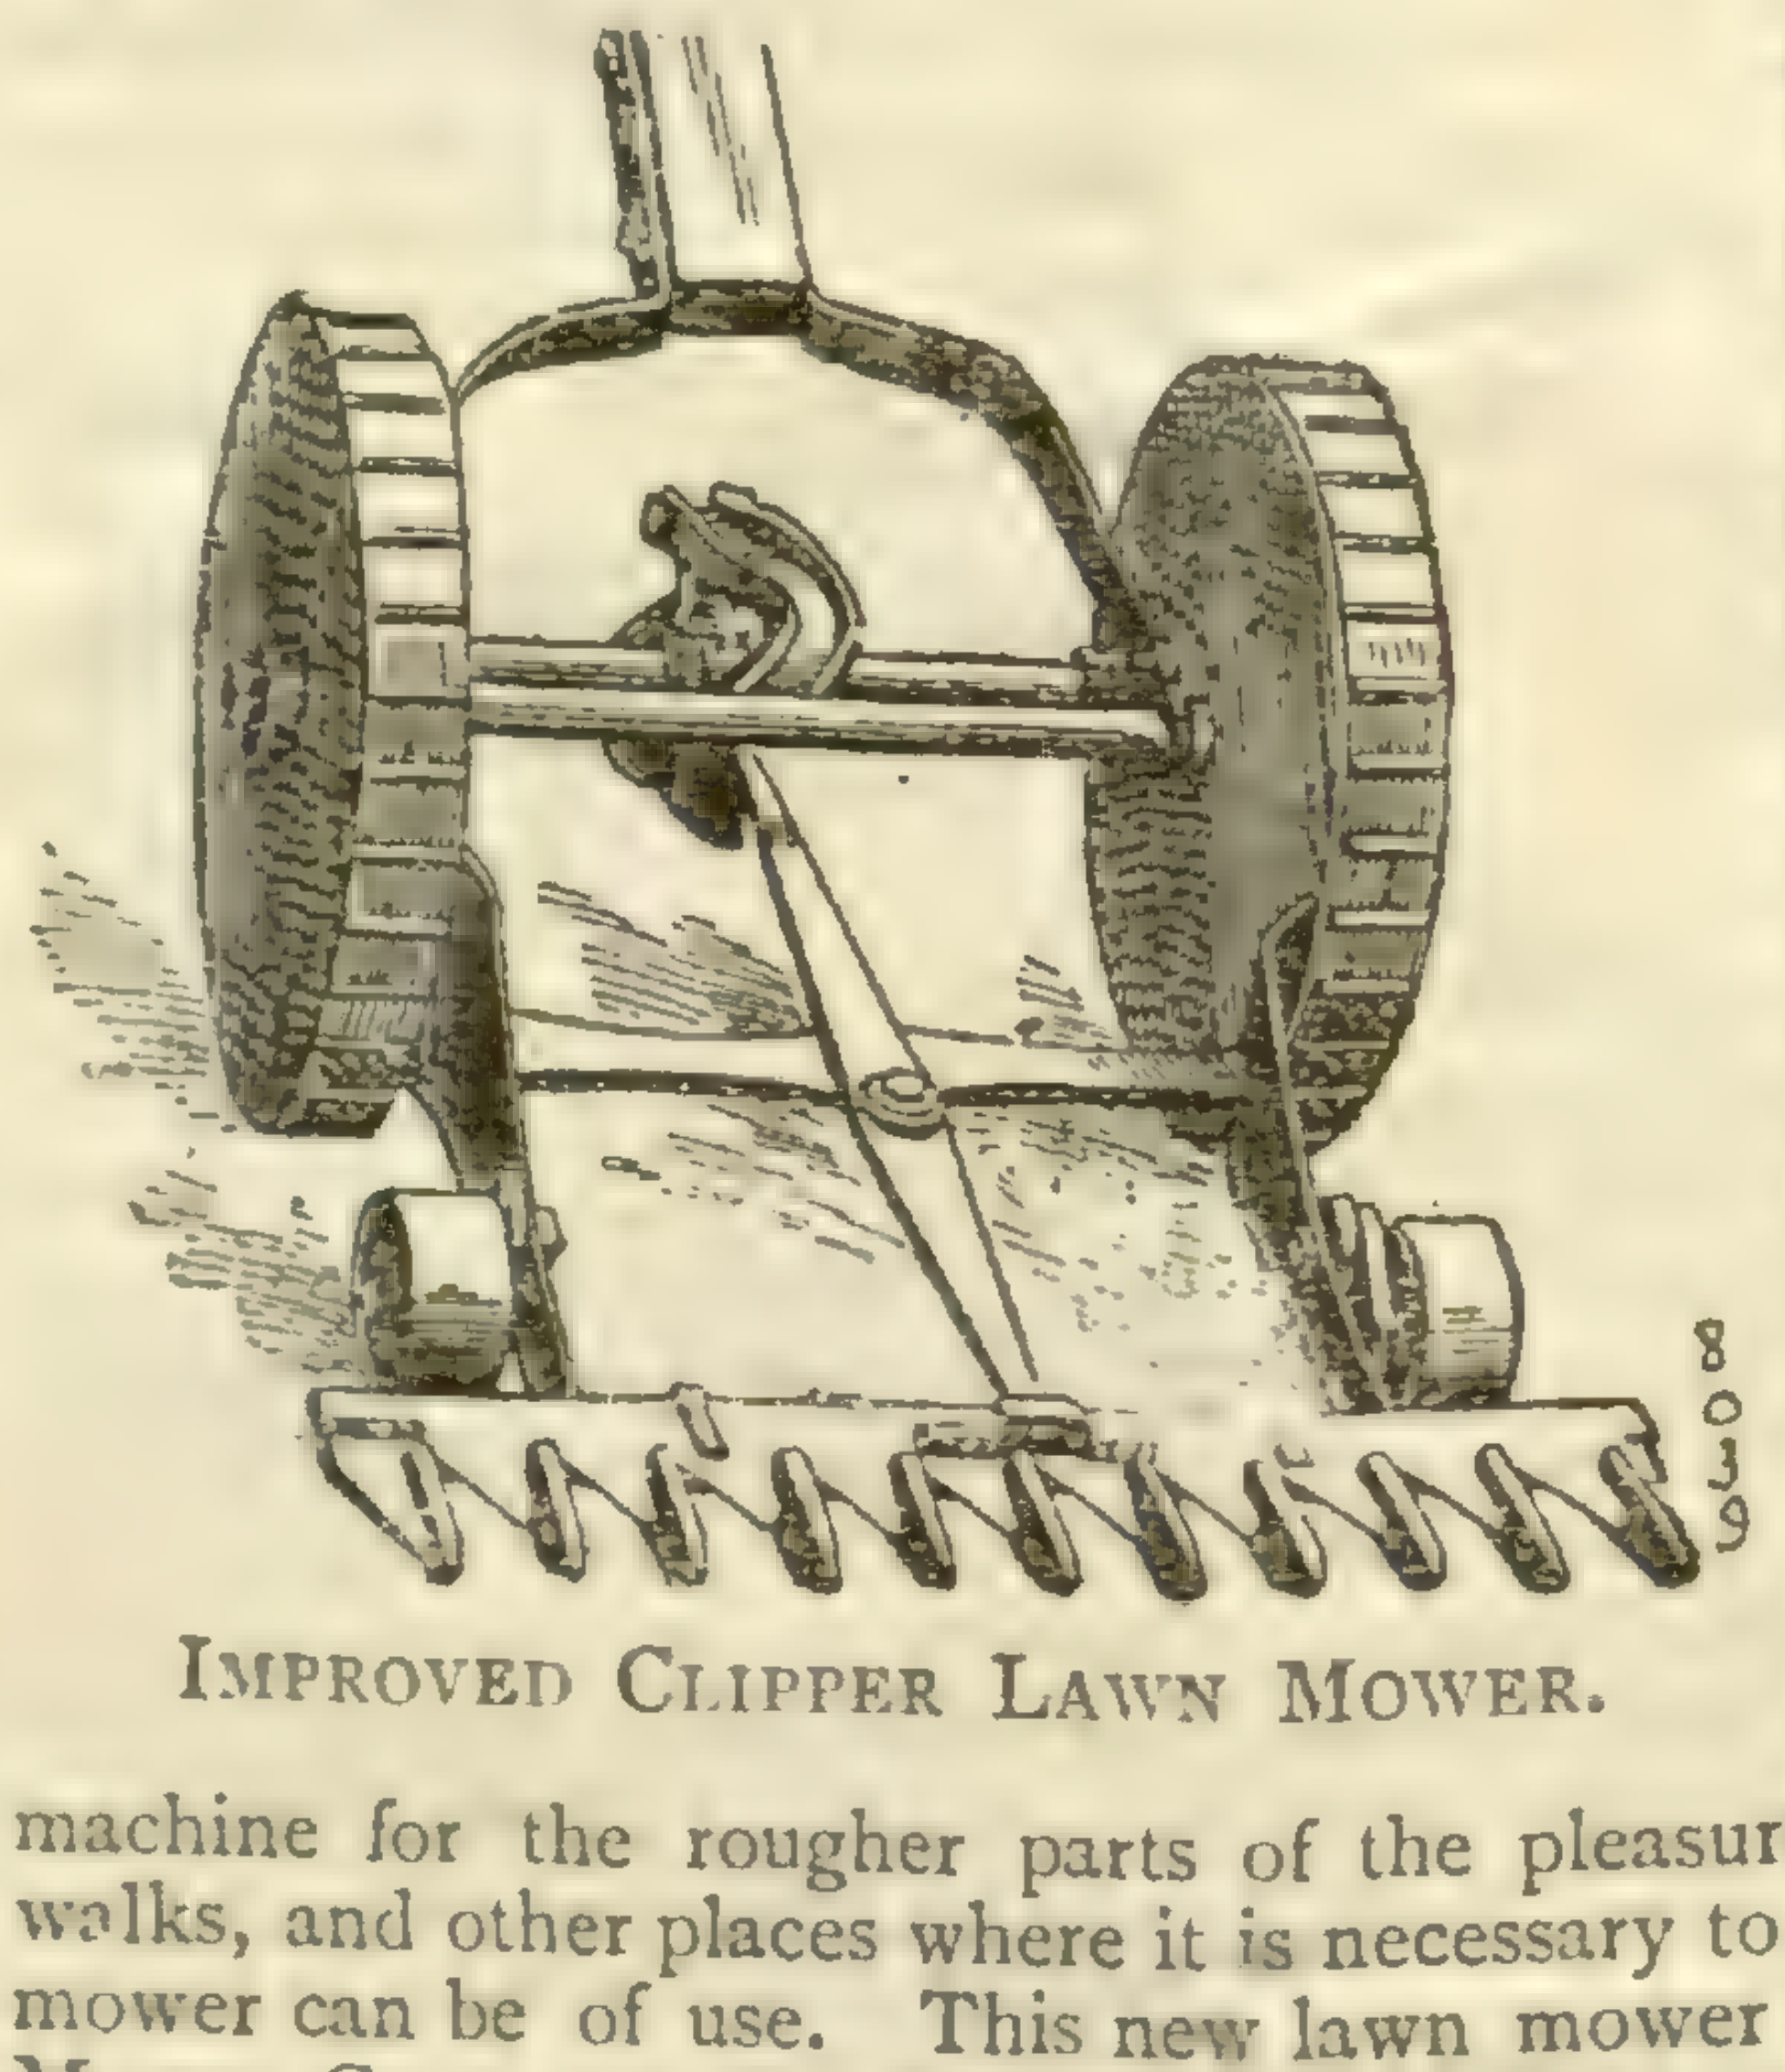
Lord Justice Rigby delivered a written judgment to the like effect.

Lord Justice Vaughan Williams differed. His Lordship agreed with Lord Justice Collins, that the cases of "Purser v. Worthing Local Board" and "The London and North-Western Railway Company v. Llandudno Commissioners" showed that *prima facie* this land covered with these glasshouses was part and parcel of the market garden, and therefore agricultural land, the occupier of which was entitled to the benefit of this exemption. The form and collocation of words used in this Act was not new as defining partial exemptions in rating cases. He could find nothing in the tenour or details of this Act to lead to the conclusion that the words "market gardens" and the other collocated words should receive a different construction, so as to exclude from agricultural land the buildings on each hereditament, whatever their character. After discussing sections 1, 5, 6, and 9, his Lordship arrived at the conclusion that the land covered with glass houses fell within the exemption, because the buildings were part and parcel of the market garden, which, by the terms of the definition, was agricultural land, and were used exclusively for the purpose of cultivating the land.

The appeal accordingly was allowed.

NEW INVENTIONS.

The Improved Clipper Lawn Mower is said to surpass other machines of its kind in simplicity. Instead of knives spirally arranged on a cylinder, the Clipper has a cutter bar and fingers, these being placed before instead of behind the front rollers. The accompanying illustration shows that the wheels travel over the ground where the grass is cut, never rolling down the standing grass with the wheels. The small gauge wheels at the side are to gauge the height you wish to cut the grass. The knives can be sharpened in the machine with a small file or whetstone, or can be taken out and ground, but they must never be sharpened anywhere except on the beveled side of the knives. There is a Pony Mower which has a cutter bar twenty-four inches long. It makes no difference to the Clipper Mower how high the grass is or how many weeds there are in it, and this renders it an extremely useful machine for the rougher parts of the pleasure ground, margins of woodland walks, and other places where it is necessary to use a scythe before the usual lawn mower can be of use. This new lawn mower is sent out by the Clipper Lawn Mower Company, Norristown, Pa., U.S.A.



IMPROVED CLIPPER LAWN MOWER.

Mr. W. Smythe.—I should like to add my meed of praise and esteem for this good gardener, so well spoken of by Mr. A. Dean. Basing Park is but nine miles from Swanmore, and coming here as I did, quite a stranger, twenty years since to undertake the making of this garden, I found Mr. Smythe a capital neighbour in every way. Many a time have I gone to him for information on what were to me knotty points, and in every instance the life-long experience of this man was at my command. I therefore know and appreciate the value of information so well, truthfully, and liberally given. Not only is Mr. Smythe a specialist, but he is one of the best all-round gardeners that I know.—EDWIN MOLYNEUX.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," [illegible] containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

The Geographical Distribution of Plants.

There is no fact better established in geology than that the earth's crust is not stable, but is constantly undergoing extensive changes and subsidences; this brings it to pass that land and water surfaces are not constant but changing, and that many regions now separated by the sea have in former times been connected, and many now connected have but lately become so. These changes have forced vegetation to perform migrations which have been small or extensive, slow or rapid, just in proportion to the change, and these have been accompanied by great changes in climate, including even such extreme conditions as prevailed in the glacial period.

Alpine Floras.

In looking at the distribution of plants in a broad way, the first feature to strike attention—according to Mr. W. F. Ganong, of Harvard University, in a lecture delivered to the Massachusetts Horticultural Society—is the constancy with which upon higher mountains we find plants characteristic of regions far to the north of them in the northern hemisphere and far to the south of them in the southern, and in all cases cut off from their brethren by many valleys and plains occupied by wholly distinct species. Thus upon the Rocky Mountains, the Alps, the Himalayas, and others are herbaceous plants which are found growing at the sea level around the Arctic Ocean. Farther down these mountains come plants which grow in southern parts of Alaska, Labrador, Northern Scandinavia, and Siberia. Now, it is plain why they can live there—the heat and moisture conditions upon the mountain side and at the sea level farther north are similar, as we have seen; but how did the plants get upon the mountains from the north? The natural means of spread of the species themselves are hardly sufficient to explain it. But the solution is undoubtedly found in late geological history. In the glacial period, geologically very late, there descended from the north a great ice sheet of enormous thickness which drove all vegetation before it. It came so far down that Arctic plants were driven south of the region in which we are now living, and Arctic plants flourished all across the United States just south of a line from about forty degrees north latitude on the Atlantic coast, running diagonally northwestward and in corresponding regions in the eastern hemisphere. Along the high mountain ranges these plants extended much farther south, finding upon them their natural conditions of heat and moisture. Then the ice sheet retreated; the Arctic plants followed it, each tending to return to its own latitude. But along the high mountains the conditions did not change much, and the Arctic plants found upon them homes, where the species of the lowlands could not compete with them. In the valleys, however, the more southern species were at home, and soon drove out the Arctic intruders. So widespread and definite was this agency that there has not been a mountain range explored in the northern hemisphere upon which traces of these Arctic plants have not been found; moreover, the lower ranges, those not high enough to reach the line of perpetual snow, like the White Mountains, have not the extreme Arctic forms upon their tops, but sub Arctic or very cold temperate forms, and these extend south along the hill ranges, ascending as they go. A very interesting point in connection with this is the fact that in the glacial period some of the Arctic and sub-Arctic forms managed to cross the equator along the highest mountain chains of the Old and New World, and established themselves in the southern hemisphere, and are there found on the mountains at the present day. Hence we have a great natural group of plants called the Arctic alpine flora, consisting chiefly of low herbs, the distribution of which is all around the northern hemisphere, upon the shores of the Arctic Ocean and southward upon nearly all mountains high enough to reach the limit of perpetual snow; and even extending, sparingly, on the great ranges into the southern hemisphere, at length reaching the sea level near the Antarctic Ocean.

The second feature is that in the southern hemisphere, we have a very similar, though much less abundant, Antarctic alpine flora, which is found near the sea level on the islands of the southern ocean, and extending northward upon the mountains of Chili, Australia, Tasmania, and New Zealand, and even up to Borneo. The phenomena of the distribution of this flora are so nearly like those found in the northern hemisphere, that it is believed its distribution can be explained by a southern glacial period.

Temperate Floras.

Proceeding next to temperate regions, we find a most marked contrast between the northern and the southern hemispheres. In the former we find the plants—the ordinary trees, shrubs, and herbs which we all know—all across Europe, Asia, and America, to be much alike in character, and the differences between the plants of different regions are rather those of relative richness or poverty in forms than of differences in the forms themselves—a point to which I will refer again. Hence, with the exception of a specially rich assemblage in the Caucasian and western Mediterranean region, all the plants of the northern temperate zone are grouped into one flora called the intermediate or temperate flora, and the rich exception of which I spoke is appropriately called the Mediterraneo-Caucasian flora. This latter is exceedingly rich in species, six-sevenths of those of all Europe belonging to it. Now the uniformity of this northern temperate flora is very fully explained by what is known of its history. Around the Arctic Ocean, and at several points in Greenland, Spitzbergen, Siberia, and other places, there are found abundant fossil deposits of plants in Tertiary rocks, which fossils are undoubtedly the remains of the ancestors of our living north temperate vegetation. Not only are the species of the fossil and living forms very similar, but in many cases they appear to be identical. Our north temperate flora, then, in the Tertiary period, lived and flourished all around the Arctic Circle and within it, and probably extended to the North Pole itself. Then great climatic changes drove it southward, and it peopled all Europe, Asia, and America with a similar flora. This was subsequently driven to the south by the glacial period as we have noticed, and in the changes attendant upon that process and its return northward parts of it suffered severely.

In Europe this flora is for the most part a poor one, having much fewer species than our own. This is explained, doubtless, by the fact that in Europe the mountain ranges run east and west, and as the glacial sheet advanced southward, the plants of Central Europe were caught between it and the increasing local glaciers from the Pyrenees, Alps, Apennines, and Caucasus; there being little chance for escape, many of the forms were exterminated, particularly those not having natural means of wide dissemination, and many of those which escaped the icy jaws of the glaciers were pushed across the Mediterranean. This they were unable to re-cross when the glacial ice-sheet retreated, and but few of the exiled forms could return to their homes again. That this was the true course of events is rendered nearly certain by the fact that these missing forms are found fossil in late deposits in Central Europe, showing that they existed there anterior to the glacial epoch. Central Asia has to some extent suffered in a similar way, and Greenland had its flora swept off into the sea, and it has not now the plants to which the climate of its southern part entitles it. But the conditions were very different in Eastern America and in Eastern Asia. Here the mountain ranges run north and south, or nearly so, and in Asia the great ranges end before they reach the sea. Thus a free passage was open along which the plants travelled south out of harm's way, and returned again when the enemy retreated. Hence, the floras of Eastern America and Eastern Asia are both exceedingly rich in species and most strikingly alike, each having preserved nearly all of its species through the vicissitudes of glacial times.

Peculiarities of Distribution.

But why is not the flora of Western America rich like that of Eastern America? This question is not so easy to answer. It is true the Rockies run north and south; why were not all the western plants preserved? Several causes have contributed to destroy them, one of which is the extreme unevenness of the region west of the great mountains, and hence the crowding and extermination of some species, and also the fact that the very uniform climate of California is not so favourable to the northern species accustomed to more variable conditions as it is to the more southern forms of Mexico; and these latter have travelled in large numbers into California, and possibly by direct competition have exterminated some species, and certain other geological conditions have doubtless contributed somewhat to the same end. But the fact remains that, like that of Europe, the flora of the Californian region is poor in temperate species, while those of Eastern America and Japan are rich and much alike.

In the southern hemisphere we find a very different state of things. There the great continents, separated from each other from a most remote period, possess floras strikingly distinct from each other, so that it is necessary to assign to each great body of land its own distinct flora. This gives us the Australian flora, showing some slight traces of connection with the region to the north of it, and with New Zealand. Australia has so long been separated from the other bodies of land that its flora has had time for a great deviation from that of other countries. Indeed, it is notorious for its unlikeness to that of any other country. Next, the Andean flora, that of South America, which shows some slight connection with that of New Zealand and Australia.

Then the Mexico-Californian flora which extends up the west coast of America from Chile to Mexico and into California, being the source of many of our present Californian species; and lastly, the South African flora, one that is very rich in species and remarkably varied. And just as our north temperate plants have representatives on the mountains far south of them, so these southern floras have some of their members on mountains far away to the north. "The plants of Fuegia extend northward along the Andes, ascending as they advance." Australian genera reappear in Borneo, and even cross to China and Japan; New Zealand forms are upon the mountains of New Caledonia; South African, in the lake region of Africa, in North Africa, and even in the Canary Islands and Asia Minor. In all these cases the southern, like the northern, forms ascend the mountains as they approach the equator, and descend toward the sea level after they have crossed it. Now, what is the history of these widely-separted regions? There seems every probability that in times far back all these floras came, not from the south, but from the north; and the time when they had a common home there is so remote that the floras have had time to diverge greatly. That this is the correct view is sustained by the fact that these southern floras are much more like those immediately to the north of them than they are like one another; that there is no evidence of a southern continent from which they could have come; that while most peculiar species of the south have relatives, either living or fossil, in the north, none of the northern forms have fossil relatives in the south.

Floras of the Tropics.

Lastly we come to the tropical floras, characterised by great abundance of all kinds of vegetation, and with a preponderance of succulent, moisture-loving plants. Of these there are three, remarkably distinct, if we consider the relationship of the plants of which they are composed; very similar if we consider their general appearance. They are: the American flora, reaching its highest development in the valley of the Amazon. It is excessively rich in species and luxuriant in growth. Secondly comes the African flora, still imperfectly known, but also very rich. Many of its general characteristics have been vividly sketched for us in Mr. Stanley's latest work. And thirdly is the Indo-Malayan flora, including India and all the East Indian Archipelago, with the Malay Peninsula, and extending even to Australia and Japan. The relationships of these three are sufficiently well known to indicate that while they differ much from each other, they are more alike than are the floras of the south temperate zone we have considered, a fact tending to show that the former may have been connected with each other more recently than the latter. From this the step is but a short one to the theory some years ago propounded by an English naturalist, that all the floras, and therefore all the plants of the earth, have originated in the northern hemispheres and that they have spread southward in successive great waves, the more southern and older floras being the most ancient of these, the more northern floras later in time.

In conclusion, to sum up the whole matter, I hope I have shown that while the causes controlling the distribution of plants are many, and rendered tremendously complexed by their interaction, we can separate out the principal agencies and trace their effects; that the agencies limiting distribution are, the needs of plants with reference to the amounts of heat and moisture to which they have respectively become adapted, and also by the past history of each plant, placing it in some one region, and not in all to which it is adapted; and finally, that the active distributing agent, aside from the comparatively feeble efforts of the plants themselves and man's insignificant effect, has been the successive migrations compelled by past climatic and geological changes, and these migrations have resulted in the distribution of all plants over the earth's surface into those different groups or floral which we have just considered, which groups probably all came in a series of great waves from the north.

Forced Rhubarb.—How welcome at any time, but especially in such a season as the present, when apples are scarce and dear, is forced rhubarb. Yet, all the same, how exceedingly dear it is! Sold in bundles of three stems for threepence, or at the rate of one penny per stem of about twenty inches in length, no wonder it is not for the million in the middle of March, as it will be some few weeks hence. But it seems as if there is great room for an expansion of rhubarb forcing. What may be the price obtainable by the grower it would be interesting to hear, but the price I name is what the consumer has to pay. Bottled gooseberries are about the same price relative to product, as these do not shrink, and they are quite as palatable as are those gathered in June. Whilst it does seem as if the pulping or jam-making of fruit was rather overdone, there seems no doubt whatever but that good bottled or tinned whole fruits are in great request, and there is not the least probability that the public taste will vary, except in the direction of wanting much more.

EXHIBITIONS AND MEETINGS.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY, March 13.

THERE was a fairly good attendance at the annual meeting of the above friendly society, which took place at the Caledonian Hotel, Adelphi. Mr. George Wythes occupied the chair. Having read the minutes of the previous annual meeting, &c., the Secretary (Mr. Collins) read the report and financial statement for the past year.

REPORT FOI 1897.

In presenting the annual report and balance-sheet for the year ending January 10, 1898, the committee have great pleasure in stating that the society continues in a prosperous condition. Sixty-eight members joined during the year, twenty-one lapsed, and three died, one being a lapsed member, and the amounts standing to their credit in the ledger have been paid to their nominees. The membership is now six hundred and eighty. The amount of subscriptions paid by members to the benefit fund, including arrears for 1896, was £1,064 14s. 2d. The amount paid to sick members was £232 9s., there having been forty-six members on the fund. The amount of subscriptions to the Benevolent Fund from honorary and benefit members was £129 1s., and £23 10s. has been granted in small amounts to four members from this fund.

The Convalescent Fund is progressing favourably. It is suggested that this fund should now be incorporated in the rules. The amount received for this fund, including donations at the annual dinner, was £28 0s. 8d. Two members received £1 10s. each from this fund. The Management Fund shows a balance of £77 15s. 7d., having benefited to the extent of £10 10s. by donations at the annual dinner; also £10 6s. 6d. by advertisements in the annual report. The annual dinner was again held at the Holborn Restaurant. H. B. May, Esq., occupied the chair, and fulfilled his office in the best manner possible, and everyone present thoroughly enjoyed the evening's entertainment. The accounts were audited by Messrs. W. Gunner and G. Dixon, and found correct. The committee again invite members of the craft to join this society, and so lay by something for a rainy day, taking for their motto, "Union is Strength."

FINANCIAL STATEMENT.

Limits of space prevent us from giving in detail the balance-sheets of the four funds, but we may state that the balance in hand on the Benefit Fund is £9,857 11s. 5d., as against £8,834 5s. 5d. at the commencement of 1897; the Benevolent Fund has increased its balance on the right side from £2,604 0s. 5d. to £2,805 3s. 9d., and the Convalescent Fund from £304 6s. 6d. to £338 3s. 8d.; the balance in hand on the Management Fund is £77 15s. 7d., which compares favourably with that of £44 14s. 7d. last year. The treasurer's statement of accounts shows the actual working of the year, and is as follows:—

TREASURER'S STATEMENT OF ACCOUNTS.

Total invested money... ... ... £13,100

Audited and found correct.
GEO. DIXON,
W. GUNNER, } Auditors.

Mr. Hudson, who read the treasurer's accounts, informed the meeting that he had obtained a valuation of the society's investments, and at their middle value, as quoted on the Stock Exchange recently, the Nottingham Corporation Stock, £5,500, was worth £6,380; Manchester Corporation Stock, £1,600, worth £1,760; West Bromwich Corporation Stock, £3,300, worth £3,5[illegible]; Cardiff Corporation Stock, £1,100, worth £1,155; York Corporation Stock, £600, worth £642; and South Indian Railway Government Stock, £1,000, worth £1,225. Thus their £13,100 invested now had a total value of £14,742.

Mr. Wythes, in moving the adoption of the report and balance-sheet, said: It has been a very great pleasure to me to listen to the most satisfactory account of the working, financial and otherwise, of this society for the year ending January 10 last. From inquiries made I have been enabled to discover something of the general progress of this excellent society. The advance has been simply astonishing; and when the merits of the society, however, are carefully considered as they should be, by every gardener in the kingdom, it comes as a matter of surprise to me that the increase has not been more rapid. There can be no question as to the sound financial basis of the society, for there is an invested capital at par value of £13,100, but which I am informed by the treasurer, is actually worth £14,742 10s. There are about 720 paying benefit members now on the books of the society, and the investments work out at an average of nearly £[illegible] 10s. 8d. per member. Some members of course have close upon £90 to their credit, but these are the oldest members, and there is less, as a matter of course, to the younger ones. If one turns to the management expenses—and here let me pay a well-deserved compliment to the officers and committee for the admirable way in which the affairs of the society are being managed—there is this gratifying fact to be noted, viz.: the entire working expenses of the past year are only about six per cent. of the income. Members and non-members should note this, and contrast it with the working of other societies of a similar kind. It may well be asked, Can other societies of any standing show such a sound financial condition as that of the United? I think not. There must therefore be some other reason why the members do not increase more rapidly than they do. Personally, I am disposed to think it is caused by negligence and apathy; some do intend to join perhaps, but put off doing so from year to year. Some think possible they can do better by joining mixed societies. Can they? I think not. It must be very evident to everyone who thinks the matter out that large societies with many branches cannot possibly be worked so cheaply as the United, controlled by a central board of management. There is a fascination, perhaps, in the regalia and paraphernalia some societies have, but this does not benefit the individual members. The investments of the United during the past year, as we have just heard, amounted to £1,200, or £100 per month. For the past two years £1,100 each year were the sums invested. Thirteen years back, I have been informed, there was invested the sum of £301 17s. 6d., which for that year (1884) made up the total of invested monies to £3,000, so that from 1884 to 1897 the increase at par value has been more than £10,000.

The members should not lose sight of the fact that the Executive Committee are still enabled to allow each one respectively 3 per cent. per annum on the balances standing to their account in the ledger. This allowance of 3 per cent. cannot go on many more years at the present price of sound trustees' stock, which do not realise now more than 2½ and 2¾ per cent. The more one considers the rules of this society, the more disposed will they be, in my opinion, to give every credit to the originators of the United. I am glad to see here to-night some of the original members who have never drawn one penny from the funds. Every member should do his best to obtain fresh members, never missing a chance to press home the essential features of the society, and bearing in mind the motto of the society, "Union is strength!" I have not the slightest doubt that there are many candidates for the pension of the Gardeners' Royal Benevolent Institution (a society I am much interested in) who would be only too glad if they were members of the United; yet many do not appear to have belonged to any society at all. I hope, when the report of the past year's working is noted in the horticultural Press, that many more will be induced to join. I have not the slightest doubt that these reports and notices have been the means of inducing many gardeners to join the ranks, and the willingness with which any notice of the society is inserted by the several editors deserves every possible recognition. I should like to draw attention to the "Voluntary Convalescent Fund." Its name describes its use very well, indeed. What an advantage this fund should be to young gardeners throughout the country; those, for instance, who are either in bothies or lodgings, and who after an illness would be greatly benefited by a change of air. When I and others in this room were in a bothy or lodgings, we had no such opportunity as this fund affords of regaining health and strength. To young gardeners, therefore, who are moving from garden to garden, I would say, "Bear this fund in mind!" In conclusion, I would refer to the remarkably low death-rate which, in spite of what some say to the contrary, points to the healthiness of gardeners in general and their longevity in a marked manner. Then, of course, it must be added that our profession will bear a very favourable comparison with any other for those cardinal virtues which go to build up good character and healthy bodies. I have much pleasure in moving the adoption of the report and balance-sheet of the year 1897.

Mr. W. Marshall, who may be regarded as the originator of the society, seconded Mr. Wythes' proposal. He contrasted the present state of affairs with that which obtained in the childhood of the society and expressed his thanks to Providence for sparing him to see a scheme for the benefit of gardeners attain such a prominent and sound position. He congratulated the society upon its management and present position. The report and statement being adopted unanimously it was decided, upon the proposal of Mr. Cole, that 2,500 copies be printed and circulated.

The next business was to elect four committeemen in the place of those retiring, the retiring members offering themselves for re-election. Those elected were Messrs. Thomson, Wheeler, Cook, and Wood. A vote of thanks to the treasurer, proposed by Mr. Cole, was responded to by Mr. Hudson, who once again pledged himself to do all he could on behalf of the society. The Chairman having warmly congratulated the society upon having such a hard working and painstaking secretary, proposed the re-election of Mr. Collins to that post. Mr. Collins was unanimously re-elected and thanked the members for their confidence in him. So far as we can gather Mr. Collins receives the stupendous sum of £35 10s. for his services during the past year. Votes of thanks to the committee, the trustees, and horticultural press, were all unanimously passed. A vote of thanks to the chairman, moved by Mr. W. Marshall, and seconded by Mr. Cook was carried with acclamation.

SPECIAL GENERAL MEETING.

A special general meeting followed the annual general meeting, and was held to consider the advisability of altering Rules 8 and 14, and of adding a new rule to be numbered Rule 18A. On the motion of Mr. Hudson, it was unanimously agreed to alter "£20," in Rule 8, to "£30," this raising the salary of the secretary in future by £10. It was the opinion of the meeting that even with this [illegible] the secretary would not be by any means overpaid. Mr. Burge proposed, and Mr. Cole seconded, that after the words "lower scale" in Rule 14 the words "with the privilege of increasing this to," should be added. This rule has reference to the two scales of payment in vogue. The addition was agreed upon after it had been pointed out that the conjunction "and" following "lower scale" in the old rule would have to be deleted. A proposition to strike out the word "successive" after "twenty-six" in Rule 14, relating to the amount of full sick pay any member is entitled to receive, was moved by Mr. Thomson and seconded by Mr. Winter, both of whom showed that it was necessary to omit the word "successive" to prevent any imposition upon the society. The old rule would allow a member to have, say, twenty-five weeks' full sick pay, and then another similar period after an interval of perhaps a fortnight or so. The idea of the movers was to prevent any one member from having more than an aggregate of twenty-six weeks' full sick pay during any period of fifty-two weeks. An independent listener to the discussion would have inferred that the society had been imposed upon or had barely escaped imposition, but this was shown not to have been the case. It was eventually decided to omit the word "successive" in the rule under notice.

Mr. Cole moved that the Convalescent Fund be now incorporated into the society's affairs by rule, and that a new rule, to be called Rule 18A, should be added to those already drawn up. Mr. Marshall seconded the motion, and it was unanimously agreed to adopt the new rule, which reads thus: "Voluntary Convalescent Fund.—The object of this fund is to give members a change of air during convalescence. The Committee of Management to have power to relieve members of this society from this voluntary fund as they may deem advisable. All cases must be recommended by a duly qualified medical practitioner."

A further vote of thanks to Mr. G. Wythes for continuing as chairman concluded the proceedings.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.

THE monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport a few days since. Dr. J. Groves, B.A., J.P., presided over a large attendance of members. Mr. J. H. Larkin, Los Altos, Sandown, prepared a paper on "The Cultivation of Asparagus," of which the following is an abstract: Asparagus, said Mr. Larkin, thrives best in a deep, sandy, well-manured soil. When I have a new bed made I select a nice open piece of land, and have it deeply trenched and well manured. I prefer beds about four feet six inches wide, and planted with three rows of plants at about sixteen inches from row to row, and the plants nine inches apart. I generally procure good one-year old plants. The best time I consider for planting is from the middle of April to the middle of May. Of course planting can be done earlier, but I believe it to be a mistake to plant asparagus too soon, as if it should be a cold spring the roots are so liable to decay. Watering assists growth in dry weather, and liquid manure is very beneficial to poor soil, also a little salt occasionally during early growth. I believe in clearing off the grass early in the autumn before the seed berries fall, as it is a mistake to leave them to ripen and fall on to the beds, as, in consequence, a considerable number of seedlings come up and cover the bed, which are quite as troublesome as weeds, and should be pulled up. After the beds have been cleared of weeds and grass I generally give a good dressing of rotten manure and seaweed, and let it lay till March; and if the weather is inclined to be fine, we simply take a wooden rake and draw off the rough material on the surface. It is important not to exhaust the crowns by cutting too late in the season, unless we have a very late spring. I do not cut after the third week in June, and am careful not to allow an inexperienced person to cut the heads, as they so often injure those just pushing from the crowns, and reduce supplies. I have had nothing to do with forcing asparagus of late years, but when occupying a position where early supplies were required, we used to endeavour to send to the kitchen at Christmas forced rhubarb, seakale, and asparagus. We used to use ordinary brick melon pits, filled in with prepared stable manure and leaves well trodden down to within one foot of the glass. Two days afterwards this was covered with a layer of mellow soil about three inches thick. As soon as the fermenting material had arrived to a safe temperature, from 70 to 80 degrees, strong roots were carefully lifted and placed closely together on the warm soil and then covered with some more prepared soil. The manure should be well trodden to prevent too much sinking and to keep in the heat. In fact, you want the bed to be prepared in much the same manner as for mushrooms—that is, firm and solid. The only attention required afterwards is to cover up the frames from frost and to give an occasional watering, a little salt being dissolved in the water. A little ventilation will be required in mild weather. If blanched asparagus is required, that can readily be obtained by excluding the light. Though, as I have said, I have myself cut asparagus on a Christmas morning I do not recommend forcing asparagus quite so early, as by commencing to force in February much better results are obtained, the flavour being more highly appreciated. The variety I prefer is Connover's Colossal, but there are several other varieties in cultivation of much merit.

Mr. R. Parsons obtained the association certificate for cultural merit for a collection of cyclamen. After some discussion the forms of certificates to forthcoming Island shows, and the question of printing the monthly proceedings, were adjourned to another meeting.

It was decided to hold the April meeting at Shanklin, and that it should take the form of an exhibition of spring flowers. The arrangements of excursions were left in the hands of the secretary. Twelve new members were elected.

THE SCOTTISH HORTICULTURAL ASSOCIATION'S MAJORITY.

THIS society, which is now between six and seven hundred strong, celebrated its sturdy majority by a supper, under the chairmanship of its president, Mr. Todd, on Wednesday, March 9, in the Bemrose Hotel, Princes Street, Edinburgh. There was a good gathering of representative horticulturists, the croupiers being Messrs. Dunn and R. W. E. Murray. The Corporation of Edinburgh were ably represented by Bailies Hay and Mackenzie; visitors by Messrs. Robertson (Glasgow), and W. P. Melville (Dundee). Among other members and friends were: Messrs. Dunn, Janes, Grieve, Loney, D. T. Fort, W. McKinnon, A. Mell, W. Carmichael, Byron, D. P. Laird, R. Laird (the energetic secretary), and many others. The usual loyal toasts were given by the President in patriotic and enthusiastic terms. In the absence of Mr. R. W. E. Murray, the Secretary (Mr. R. Laird) proposed "The Army, Navy, and Reserve Forces." Mr. Mackenzie then proposed "The Lord Provost and Magistrates of Edinburgh," gracefully acknowledging the assistance received from the Corporation in carrying through their great shows. For many generations it had been the good fortune of Edinburgh to be ruled by a body of intelligent, patriotic, and far-seeing men. He could look back to 1851, and was simply astonished at the progress they had made in various directions, especially in the sanitation and adornment of their fair city. Bailie Hay responded in an eloquent and able speech. As great educators, it afforded them much pleasure to foster the love and culture of flowers, and to know that their services in these directions, amid their ardous duties, were appreciated by the members of this association and kindred societies. Bailie Hay subsequently, in proposing the toast of the evening, "The Scottish Horticultural Association," dwelt on the small beginnings of their society in the Bible Society Rooms. They had been banded together for the noble art of horticulture, and had now reached a strong and healthy majority. They had been most successful, and he was sure the citizens of Edinburgh owed them a deep debt of gratitude for the privilege of visiting their chrysanthemum show, which was the admiration of all classes of people and second to none in the world. He hoped the corporation would always be in touch with them, and would never stint their donations to this and other kindred institutions. He gave place to no one in his love and admiration for their association, which had done so much good in the past and was capable of doing even more good in the future. The toast was most cordially received, and responded to in able and eloquent terms by the President (Mr. Todd). He said they had done what they could to deserve success. The public had backed up their efforts, and ample success had followed. They had had no ebbtide, and their success had gone on year after year. They had added to their numbers and increased their usefulness. Since the chrysanthemum shows were established they had gone on with unvarying success. They were most grateful for all the help rendered by the corporation. The public had come to look upon their show as one of the most attractive entertainments of the year in their city. With every fresh success they had attempted to strengthen and widen their attempts at bringing together the very best in the way of chrysanthemum and other floral products, and those certainly culminated in their last show. They had also, he thought, done wisely and well in devoting part of their income to charity. Mr. J. P. Laird proposed "Gardeners and Gardening," to which Mr. Dunn replied; Mr. A. J. Johnstone "The Nursery and Seed Trade," to which Mr. Milne replied; Mr. Bailie Mackenzie "Kindred Societies," replied to by Mr. W. P. Melville; "The Founders" by Mr. D. Mitchell, replied to by Mr. Robertson Munro; "Commercial Horticulture" by Mr. Long, replied to by Mr. Scarlett; "The Secretary and Treasurer" by Mr. McKinnon; and "The Chairman, President Todd," by Mr. D. T. Fish. At the conclusion of a very full programme of speeches, songs, &c., which made the evening pass speedily and pleasantly, the President, in his own name and that of all the preceding presidents, presented the association with a handsome album containing all their photographs, which will prove of very considerable horticultural and historical interest later on.

D. T. F.

OBITUARY.

PROFESSOR KIRK, F.L.S., the distinguished botanist and arboriculturist, who for a long period occupied an important position in the Department of Woods and Forests of New Zealand, died a short time since in that colony. Professor Kirk, who was of Scotch extraction, spent the greater part of a long life in New Zealand, and rendered valuable service on behalf of the arboricultural features of the islands. He was a distinguished botanist, and his "Forest Flora of New Zealand" is the standard work upon the forest growths native to the islands. Since the production of his principal work he has continued, from time to time, to publish interesting monographs upon New Zealand timbers. A very valuable report on the trees suitable for forest cultivation in the colony was issued by him in 1886, at which time he held the position of Conservator of State Forests in New Zealand, and he is understood to have been engaged up to the moment of his death upon a great work devoted to the botany of Australasia.

MARKETS.

Covent Garden.

THERE is a moderate supply of fruit on offer, but prices are high and trade generally is quiet. Oranges meet a fair demand. Green vegetables are in request, and there is a moderate potato trade. Cut flower trade fairly brisk,

FRUIT.—American and Nova Scotian apples, 15s. to 25s. per barrel; English grapes, 2s. to 3s.; Belgian, 1s. 6d. to 1s. 9d. per lb.; pineapples, 2s. to 6s. each; Cape peaches, 6s. to 10s. per box; bananas, 4s. to 10s. per bunch; dates, 10s. to 12s. 6d. per cwt.; Valencia oranges, 8s. to 15s. per case; Jaffa, 8s. 6d. to 12s. per box; Canary tomatos, 10d. to 1s. 6d. per tray, 3s. 6d. to 4s. 6d. per case; lemons, 8s. to 16s. per case.

FLOWERS.—Arums, 2s. to 3s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 3s. to 4s.; Lilium Harrisi, 2s. to 4s.; tea roses, 6d. to 1s.; pink roses, 4s. to 8s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 4d. to 9d.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 3s.; Roman hyacinth, 4s. to 6s.; daffodils, 2s. 6d. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; wallflowers, 4s. to 6s.; primroses, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 4d. to 6d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 9d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

VEGETABLES.—Italian cauliflowers, 3s. to 4s. per basket; celery, 6s. to 15s. per dozen rolls; spinach, 2s. to 2s. 6d. per bushel; eschallots, 1s. 6d. to 2s.; mushrooms, 6s. to 8s. per 12 lb.; Brussels sprouts, 1s. to 1s. 6d. per half-sieve; green mint, 4s. to 5s.; parsley, 2s.; leeks, 1s. 6d.; carrots, 2s. to 3s. per dozen bunches; rhubarb, 1s. to 1s. 6d.; French lettuce, 9d. to 1s.; cos ditto, 2s. to 2s. 6d.; cucumbers, 3s. to 6s.; endive, 1s. 4d. to 1s. 8d. per dozen; cabbages and savoys, 3s. 6d. to 5s, 6d. per tally; Valencia onions, 6s. 6d. to 8s. 6d. per case; English, 5s. 6d. to 6s. 6d. per cwt.; new potatos, Canary, 10s. to 16s.; Malta, rounds, 10s. to 14s. per cwt.; French, 2½d. to 3d. per lb.

Borough Potato Market.

Supplies are light and prices unaltered, save for an upward tendency for the best stocks, a tendency that would be accentuated if the weather turned colder for a week or so.

Dunbars, 120s.; Scotch Magnums, 100s. to 110s.; Hebrons, 100s.; Snowdrops, 90s.; Bruce Maincrop and Sutton's Regents, 90s. to 95s.; Reading Giants and Saxons, 85s. to 90s. per ton; Belgians, 3s. 3d. to 3s. 9d.; Germans, 3s. 6d. to 4s. per bag.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates.

Fasciated Holly Growth.—J. H, W., Handsworth: We are obliged to you for the specimen sent; it is a monstrous example of fasciation and remarkably interesting. We hope to allude to the matter in a future issue.

Roses in Pots.—W. J. T., Bristol. Prominent articles on the cultivation of Roses in Pots appeared in our issues for June 27, 1896, and October, 17, 1896. Application for these and any other back numbers of the GARDENERS' MAGAZINE you may require should be made to the publisher of the GARDENERS' MAGAZINE, 4, Ave Maria Lane, E.C. We can only on very special occasions reply to correspondents through the post.

Diseased Violets.—S. W., Portslade: Since the receipt of letter and specimens we have not had sufficient time to investigate the disease properly. There is a fungoid attack, but probably this is a result rather than the cause of failure. The effect produced upon the foliage is precisely that we should expect to find if the violets had been excessively fumigated, and the frames kept closed during a period of bright sunshine. The soil appears not to be the cause of failure, judging from the roots sent. A strong insecticide may also have been the cause of failure. We should be glad to hear whether or not the violets were fumigated severely.

Marjoram.—A. B., Henley: The term Marjoram is a collective one, often used as a generic title in gardens for the various species of Origanum grown as herbs. The most popular species is Origanum Majorana, formerly known as Majorana hortensis, whence its garden name. This is catalogued usually as Sweet Marjoram or Knotted Marjoram, and occasionally as Garden Marjoram, all three names referring to the same plant. Pot Marjoram is Origanum Onites, while the Common or Wild Marjoram is the native Origanum vulgare. O. Majorana is a native of North Africa, and O. Onites comes from the Mediterranean shores. The former is not an annual, although being but half hardy in this country it is generally treated as such.

Failure with Hyacinths.—J. G. C., Birmingham: The failure of hyacinths to properly complete the stem that bears the flower-head may be due to one of two causes. There may have been a severe check of some kind just as the spikes were becoming prominent; or, and as is most likely the case, the bulbs were not properly ripened last year. Unless great care is exercised some "green" bulbs are likely to find a place in a consignment, especially if other than the very first-class bulbs are purchased. With regard to the decay of roots when hyacinths are cultivated in water we have not seen this occur; we presume, however, that the fault lies in keeping the water in the glasses at a higher level than the base of the bulb. We find it best to keep the surface of the water a quarter of an inch below the junction of root and bulb.

Failure of Peach Tree.—A. C. R., Frome: The failure is due to improper soil and a fungoid attack that took advantage of the weakened condition of the tree. What the fungus is we cannot say from the account you send or the tiny specimen of wood. The best thing to do is to destroy the tree and obtain a new and healthy one. It would take a lot of time and trouble to bring the specimen back to health again, and in any case you are likely to lose two crops of fruit. If you are determined to try and restore health, then wash the roots clear, cutting back all that are cankered or damaged; remove all dead or affected wood, and shorten the remainder considerably to induce sturdy growth. Dress the tree with a strong solution of soft-soap suds and sulphur, and place the roots in a well-drained spot and a good turfy loam.

Vine and Fern Weevil.—W. L., Bolton: The grubs sent are those of the Vine and Fern Weevil (*Otiorhyncus sulcatus*); these are great pests when once established, and do much harm to the roots of ferns, vines, &c It is generally the best plan to shake the soil from the roots of affected plants, and then wash them so as to make sure no grubs remain, and then carefully repot the subjects. The old soil should be shaken into strong brine so as to kill the grubs. If the grubs are moderately active, plunge the infested pots into warm water and leave them there for a few hours as this will cause the pests to rise to the surface, when they can be disposed of; this method should first be tried, provided the plants are well established. Do not in any case allow the grubs to pass into the pupa and then into the beetle stage or you will have trouble, especially among the vines and ferns, also with a prospect of an increased number of grubs in the pots next season.

Fruit and Vegetable Culture in Cornwall.—B., Tottenham: There is undoubtedly room for more men in Cornwall to start business in the cultivation of choice fruits, flowers, or vegetables for the early markets, but whether you would succeed or not we have no opportunity of judging; this depends largely upon business capacity and cultural ability. The best plan will be to obtain employment in the south or south-west of Cornwall, preferably in a market establishment, and remain there for at least a year, so as to have opportunities for becoming acquainted with the peculiarities of climate, soil, &c., before starting a business of your own. In any case you should obtain land reasonably near a railway station. As you do not require a high rate of pay there should be no great difficulty in obtaining employment as the result of a little judicious advertising. The GARDENERS' MAGAZINE has a large Cornish circulation, and at the same time you might try some of the leading Cornish newspapers.

Botanical Magazine.—W. T., Cowes: The earliest volumes of the *Bot. Mag.* are of very little commercial value when separated from a complete [illegible] or long run. We have found early double volumes of this work on [illegible] at 6d. each. When the volumes are not consecutive, as in the [illegible] of thos you have, this further depreciates their value, so that you can [illegible] expect more than 1s. per volume. You might write to Messrs. W. Wesley and Co., 28, Essex Street, Strand, London, stating the number of volumes you have and their dates, and asking what they will offer for the lot. The Messrs. Wesley are large dealers in old gardening books.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

A. S., Sheffield: 1, Davallia bullata; 2, Scirpus Holoschœnus; 3, Scirpus Holoschœnus variegatus; 4, an Iris or Moræa, send when in flower; 5, Tradescantia virginica; 6, Nepeta hederacea variegata.

K. B., Henley: 1, Pelargonium citriodora; 2, P. crispum majus; 3, not recognised, probably a seedling form; 4, P. fragrans; 5, P. Lady [illegible]; 6, P. quercifolium.

W. D., Botley: The specimen sent is Bryophyllum calycinum, a stove succulent plant of considerable interest but no great value. If a leaf is laid on moist sandy soil, in a stove, young plants will be produced from the bases of the [illegible] along the leaf margin.

Names of Fruits.—We are pleased to assist our readers as far as it is possible to do so in naming fruits, but it is absolutely necessary that they should send us good specimens carefully packed, as it is only when characteristic examples reach us in perfect condition that we are able to determine their names. We are compelled to insist on the observance of this rule, as so many specimens now reach us. We cannot undertake to name more than six varieties at one time; and both apples and pears should be sent when approaching maturity, but before they are fully ripe, that we may have the assistance of their distinctive colours in determining their identity.

A. S., Sheffield: 1, Lady Henniker; 2, Victoria; 3, Braddick's Nonpareil; 4, Dumelow's Seedling; 5, Welford Park Nonsuch; 6, not recognised, probably a cider apple.

L. M. S., Gloucester: 1, Uvedale's St. Germain; 2, Egremont Russet.

Frant: No letter or initials were sent with these two apples, so we have given the name on the postmark to facilitate identification. In the usual way we take no notice of queries or specimens sent without the sender's name and address. 1, Golden Russet; 2, Wyken Pippin.

The mean reading of the Barometer during the week at Greenwich was 29·89 inches, and that of the Thermometer 37°·7, the latter being 3°·2 below the week's average in the 50 years 1841—90. The direction of the wind was north-easterly, the horizontal movement of the air being nearly equal to the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 18·0 hours. The measured rainfall amounted to 0·01 of an inch.

ENGAGEMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 21.—National Chrysanthemum Society, Adjourned Annual Meeting at Anderton's Hotel, Fleet Street, at 6 p.m.

TUESDAY, MARCH 22.—Royal Horticultural Society, Committees Meet at 12 o'clock; Lecture at 3 p.m. on Soils by Mr. J. J. Willis.

WEDNESDAY, MARCH 23.—Torquay Gardeners' Association, Spring Show.

SATURDAY, MARCH 26.—Royal Botanic Society, Meeting.

AUCTIONS.

MONDAY, TUESDAY, WEDNESDAY, AND FRIDAY, MARCH 21, 22, 23, AND 25, Hardy [illegible] Pinks, Phlox, Gladiolus, Carnations, Violets, Iris, Cannas, Lilies, Begonias, [illegible] &c., at Protheroe and Morris's Rooms.

WEDNESDAY, MARCH 23.—Stove and Greenhouse Plants, Roses, Shrubs, Border Plants, [illegible] &c., at J. C. Stevens's Rooms.

"THIEVES! POLICE! MURDER!" are the blood-curdling cries which are [illegible] times heard in the silent watches of the night coming from the bed of some unfortunate [illegible] from what is termed a disordered liver, or dyspepsia. Horrible nightmares are a common [illegible] of these complaints, and the lives of the victims become a burden to them in [illegible] Holloway's Pills and Ointment have long been famous for the cures they have wrought [illegible] cases, because they act directly upon the liver. The Ointment rubbed on the skin [illegible] immediately to that organ, whose blood and nerves it rectifies. One trial is all that is [illegible] cure will soon follow. The Pills are also the best known antidotes for want of appetite, [illegible] and flatulency.—[ADVT.]

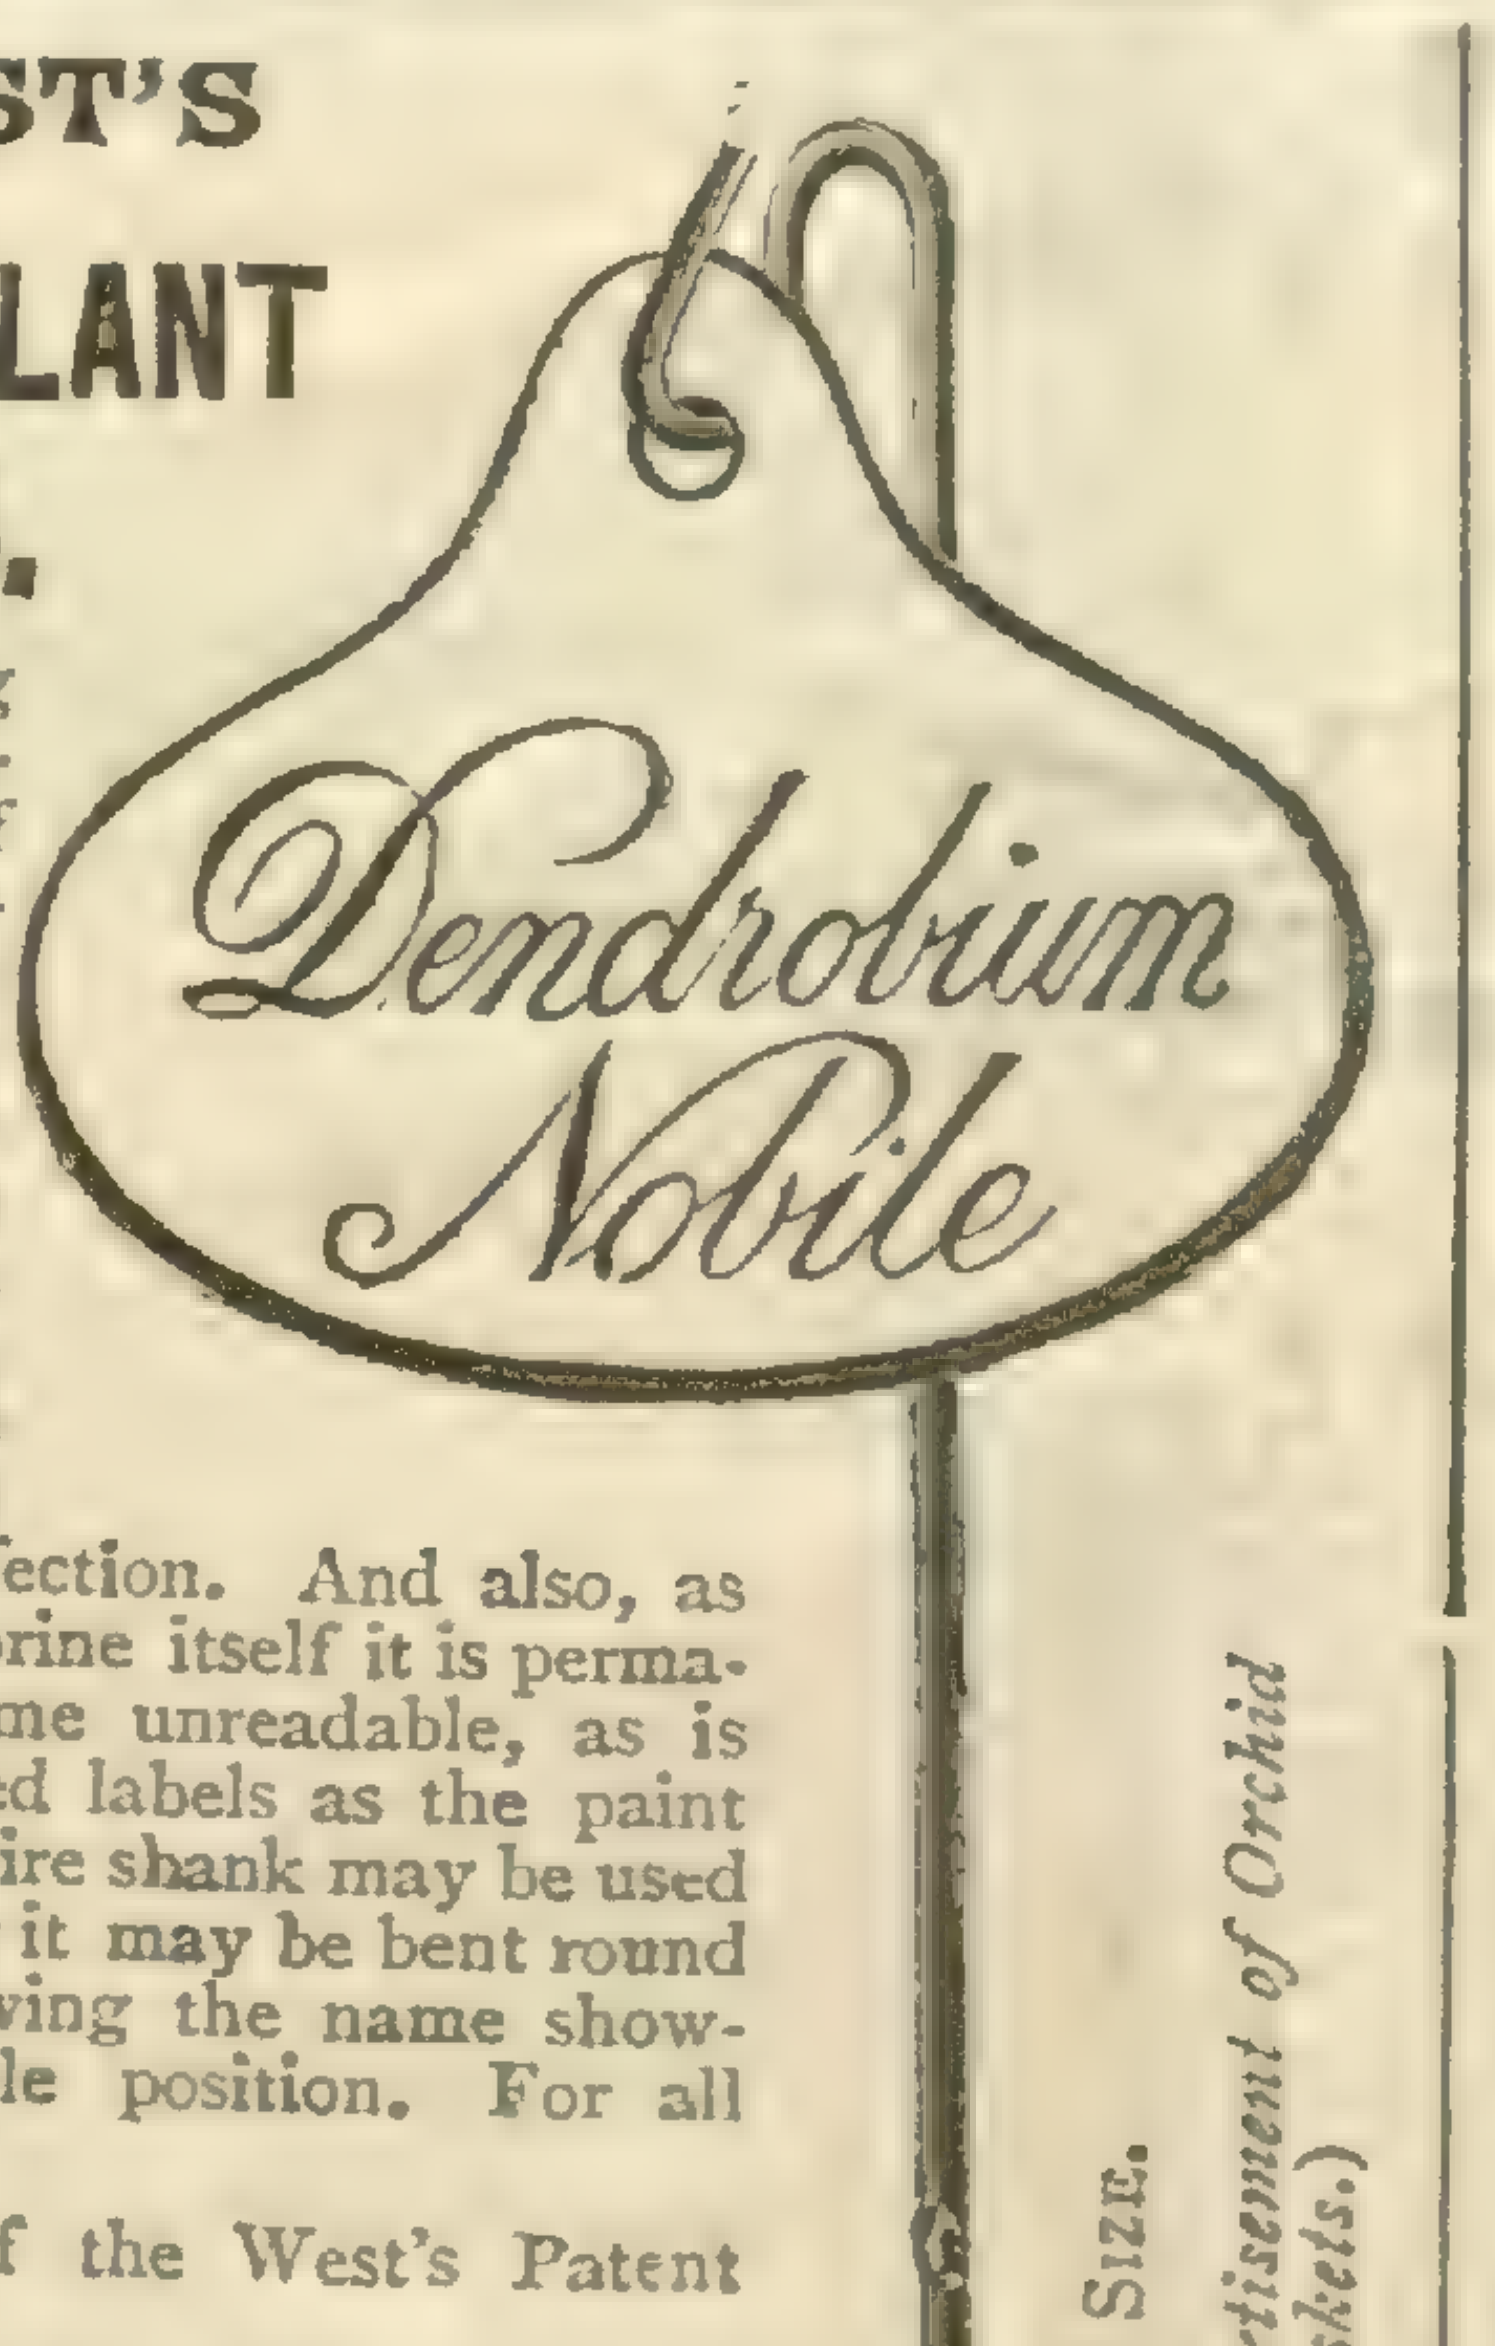
GEORGE GARSIDE, Jun., F.R.H.S., LEIGHTON BUZZARD, BEDS.

THE WEST'S PATENT IVORINE PLANT LABELS.



FULL SIZE.

(See also our advertisement of Orchid Baskets.)

The "Ivorine" Writing Disc, which is to be written upon, being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon by a common lead pencil or pen and ink, it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, and does not become unreadable, as is the case with all painted labels as the paint gets old. The copper wire shank may be used as per the illustration, or it may be bent round the stem of a plant, leaving the name showing in the most readable position. For all horticultural purposes.

Samples and Lists of the West's Patent Specialities post free.

Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.

Supplied by all Nurserymen, Florists, &c.

PRICE 6s.

RUSTIC ADORNMENTS FOR HOMES OF TASTE.

BY THE LATE SHIRLEY HIBBERD.

New and Revised Edition by the Editor of AMATEUR GARDENING.

"This new and revised edition maintains its position as something more than an ordinary amateur's guide; it is a practical work brought up to date so as to keep abreast of fashion and taste as displayed in the floral decorations of the table, the home, and the garden. This work would make a useful present to anyone."—*The Bazaar, the Exchange and Mart.*

"We cannot imagine a more appropriate presentation book than this to persons who delight in flower and attractive home surroundings. It is worthy a place in any 'home of taste.' It abounds in useful practical hints, and is eminently readable from end to end."—*Journal of Horticulture.*

EPPS'S COCOA.

EXTRACT FROM A LECTURE ON "FOODS AND THEIR VALUES," BY DR. ANDREW WILSON, F.R.S.E., &c.—"If any motives—first, of due regard for health, and second, of getting full food-value for money expended—can be said to weigh with us in choosing our foods, then I say that Cocoa (Epps's being the most nutritious) should be made to replace tea and coffee without hesitation. Cocoa is a food; tea and coffee are not foods. This is the whole science of the matter in a nutshell, and he who runs may read the obvious moral of the story."

NEW TWINE NETTING, 2 yds. wide, 3d. per yd.; 4 yds. wide, 6d. per yd. 1 inch mesh Tanned Netting, 2 yds. wide, 1d. per yd., 8s. 100 yds.; 4 yds. wide, 16s. per 100 yds. Suitable for seed-beds and lawn tennis courts. All kinds of nets made to order. Established 50 years.—W. CULLINGFORD, 177, Markhouse Road, Walthamstow.

THOSE having Houses to Let or Sell, or Apartments to Let, whether in town or country, should send an advertisement to the "CITY PRESS. The paper is acknowledged by all to be one of the best mediums for this purpose. Prepaid terms: 30 words, One Shilling; three times for Two Shillings. Offices 148 and 149 Aldersgate Street London, E.C.

SANKEYS' famous GARDEN POTS

✻ Bulwell Potteries, Nottingham. ✻

Messrs. Dicksons, Limited, Chester, write; "The Flower Pots you have so largely supplied us with are light strong, and well made, and in every respect highly satisfactory."

Messrs. Richard Smith & Co., Worcester, write: "We beg to say that we are highly satisfied with your 'Garden Pots.' They are well made, light, yet strong, and we like them better than any other we have ever used."

Messrs. Fisher, Son, and Sibray, Limited, Handsworth Nurseries, Sheffield, write: "We have leasure in testifying that after having used your pots for the past twenty-five years, we have found them all that could be desired."

To be had from the Seed and Nursery Trade generally.

MANUFACTURERS—
CORRY and CO., Ltd., London.

The Beauty of an English Garden is a

GOOD LAWN

Yet how often one sees poor yellow, moss-grown spaces in place of green, velvety turf. The cause is poverty, constant mowing, and nothing done in the way of restoring the exhausted fertility. Stable manure is an eyesore on a neat Lawn, but

PEARSON'S CHEMICAL MANURE

may be applied with little trouble or expense, and is washed in by the first shower. Will not burn the grass as some compounds do. Apply 2 oz. to square yard any time from now to end of March, 14 lbs., **4s.**; 28 lbs., **7s.**, in Tins. ½ cwt., **12s.**; 1 cwt, **20s.**

TESTIMONIALS FREE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

SUTTON'S STAR PRIMULA (Primula stellata). A very distinct race, differing in habit and general appearance from the ordinary Primula sinensis. For general decoration of the greenhouse and conservatory these light and graceful Primulas will become very popular, and as cut flowers the sprays remain in perfection for an unusually long period. WHITE, flaked crimson, per packet, 5s., post free; MIXED, producing a variety of pretty shades of colour, including white, mauve, pink, red, and striped flowers, per packet 5s., post free.

SUTTON'S STAR PRIMULA.
Mr. R. V. Smith, gardener to J. Rolls Hoare, Esq., says, "Your Primula stellata is an ideal house plant. I have had it in the drawing-room three weeks, receiving not the slightest check. My plants are 18 inches high from seed sown last spring and very full of flower. I can advise all who have much decorating to do to grow this distinct Primula.

SUTTON'S SEEDS, GENUINE ONLY DIRECT FROM SUTTON AND SONS, THE ROYAL SEEDSMEN, READING.

KELWAY'S MANUAL OF HORTICULTURE is the best, largest, and most complete Catalogue of Plants, Seeds, and Bulbs and Gardening Guide published, and is sent post free to all customers: 1/- to others.
KELWAY and SON, Langport, Somerset.

BEFORE IT IS TOO LATE PLANT PÆONIES.—Kelway's new Kinds, in the delicate new colours. The fashionable flower—Kelway and Son made it so—and the noblest and grandest of Hardy Herbaceous Perennials. Should be in every garden, shrubbery, or park. Beautiful for cut flower. From pure white to deepest crimson through all intermediate shades of cream and pink. Carriage free on prepaid orders. The largest collection in the world. Priced slip if desired.
KELWAY and SON, Langport, Somerset.

NOW IS THE TIME TO PLANT GLADIOLI. Kelway's celebrated hybrid varieties, for flower through the autumn. Invaluable for church decoration. Remember Kelway's exhibits at the London and other shows since 1851. Half a million flowering bulbs ready, the produce of 20 acres. Priced slip if desired.
KELWAY and SON, Langport, Somerset.

NOW IS THE TIME TO PLANT DELPHINIUMS. Kelway's magnificent improved hybrids, to flower between May and August, in borders, beds, shrubbery, and drive. The most stately of all hardy herbaceous perennials. The colouring baffles description, ranging from the palest azure-blue through intense gentian to deepest metallic purple-red, also the beautiful new WHITE Delphinium Beauty of Langport. Kelway and Son brought these to their present glorious perfection. Price list on application.
KELWAY and SON, Langport, Somerset.

COMPETITION DEFIED!

OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

☞ **ALL FLOWER SEEDS CARRIAGE FREE.**

CANNELL'S NEW PLANTS.

Of the Highest Importance where PLEASURE and BUSINESS are Desired.

THERE has not certainly, during recent years, been any New Plants offered that have given such satisfaction, and attracted the public eye when exhibited, as the following:—

CHRYSANTHEMUM.—White Mrs. Filkins, the queen of all varieties for cut flowers. Every one now admits the yellow we introduced has proved a most valuable variety. This novelty is pure white, of the exact same exquisite form and character, invaluable acquisition for select decorative purposes, and for buttonholes a gem of gems, 21s. each.

CHRYSANTHEMUM.—Miss Gertie Waterer, loveliest colour, most attractive of all Pompons for cut flowers, 1s. 6d each.

CHRYSANTHEMUM.—Little Dot, quite a miniature gem, the smallest and prettiest yet seen, a new shade of colour, 1s. 6d. each.

DAHLIA, CACTUS.—The Czar, lovely shape, always reliable, brilliant crimson colour, best habit, a gem, 7s. 6d. each.

DAHLIA, LORELY.—Cactus-shape, of the most delicate La France Rose colour, a decided improvement, best of its colour, 3s. each.

DAHLIA.—Orange, Glare of the Garden, a bright orange-yellow scarlet Glare of the Garden or Fire King, for general cut flower purposes. This is by far the most useful, as valuable in its way as White Mrs. Filkins, 7s. 6d. each.

FUCHSIA.—Addington, a perfect hybrid, a cross between fulgens and cordifolia; profuse flowerer, strong grower, one of the prettiest of all the family as a pot plant ever seen. An Award of Merit R.H.S. 7s. 6d. each.

TROPÆOLUM PHŒBE.—A new shape and distinct colours, deliciously scented, and as a climber indoors during the spring and outdoors in summer it gives a new feature. 1s. each, post free. An Award of Merit R.H.S.

WITHANIA ORIGANIFOLIA.—The Pampas Lily of the Valley, a perfectly hardy Climber, and a most rapid-growing plant, somewhat like the common Tea-tree, producing an innumerable quantity of white, bell-shaped flowers; equally as suitable in smoky towns as in the country. 1s. 6d. each.

ZONAL PELARGONIUMS.—Our set of these are the most distinct and beautiful that we have had the honour of introducing. For full particulars of these, and all the above, see our ILLUSTRATED and DESCRIPTIVE FLORAL GUIDE, which will be found the very life and success of every gardener; post free to coming customers.

H. CANNELL and SONS,
SWANLEY, KENT.

THOSE having Houses to Let or Sell, or Apartments to Let, whether in town or country, should send an advertisement to the "CITY PRESS." The paper is acknowledged by all to be one of the best mediums for this purpose. Prepaid terms: 32 words, One Shilling; three times for Two Shillings. Offices 148 and 149 Aldersgate Street London, E.C.

"EUREKA" WEED KILLER,

THE GARDENER'S FRIEND.

Powder or Liquid.

Saves Time, Labour, and Money.

JOSEPH VESSEY, Gardener, Kenwick Hall, Louth, Lincolnshire, wishes to RECOMMEND a strong respectable Young Man, age 17, as IMPROVER in the Houses; has been with him three years.

JOURNEYMAN (Inside) SEEKS SITUATION; age 23; four years' experience; Inside and Out; two years previous, and 12 months last place; can be well recommended.—J. WILLIAMS, Hampworth, Downton, Salisbury.

JOURNEYMAN (Inside and Out, or under a good Foreman); age 22; bothy preferred; last two years at Fetcham Park.—G. B., Manor House Gardens, Effingham, Leatherhead.

JOURNEYMAN (Inside, or Inside and Out); age 24; abstainer; seeks situation as above; two and a half years in present situation; four years previous; can be well recommended by present Head Gardener.—A. FRENCH, The Gardens, Finches, Lindfield, Hayward's Heath, Sussex.

JOURNEYMAN (Inside, or Inside and Out), age 19; 4 years' experience; bothy preferred; good references.—F. B., Fernhill, Blackwater, Hants.

MANAGER.—Market Garden (Outdoor or or Glass combined preferred); Fruit farm or other, by thoroughly practical Man; 30 years' experience; highest references and testimonials.—MANAGER, Road View, Petersham, Surrey.

RICHARD SMITH and CO., beg to announce that they are constantly receiving application from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

SITUATION WANTED by Young Man, age 22 years; as garden labourer.—Address S. SMITH, jun., School House Farm, Newick, Lewes, Sussex.

TO SEEDSMEN. — A SITUATION WANTED in shop or warehouse; ten years' experience; excellent references; age.—E., GOODMAN, Chatteris, Cambs.

TO NURSERYMEN. — Young Man (19) SEEKS SITUATION; three years' practical experience.—Apply E. W. WELMAN, 2, Argyle Street, Reading.

TO HEAD GARDENERS.—Young Man, age 25; SEEKS SITUATION; Inside, or Inside and Out; good scythe hand; 8 years' experience; bothy preferred.—For reference apply HEAD GARDENER, West Park, Damerham, Salisbury.

UNDER GARDENER, age 20; abstainer; single; 4½ years' good character; Indoor and Out.—WHITE, 56, Branksome Road, Acre Lane, Brixton.

WANTED SITUATION for respectable Boy of 15, under gentleman's gardener.—Apply J. DARLING, South Roxton, Leicester.

Situations Vacant.

Advertisements under this heading are charged 2s. 6d. for Four lines (32 words), and 6d. per line of eight words after.

GARDENER WANTED.—A single Man; wages 25s.; partial assistance by boy; London suburb; no hot-houses.—Address, letter only, stating age, previous employers, &c., to H. B., at HORNCASTLE'S, 61, Cheapside, E.C.

WANTED, an experienced Young LADY for a Florist's shop; only those who are fully competent. Apply, stating full particulars, salary, &c., to RIX, Florist and Nurseryman, Bexhill-on-Sea, Sussex.

WANTED Young MAN as Improver where Orchids are extensively grown.—Apply, JAMES SMITH, The Ferneries, Ulceby.

WANTED, at once, Young MAN, thoroughly used to general work of a small nursery; Inside; age about 22. Also YOUTH about 17, well used to the general work of the nursery.—Apply G. RAINBIRD, Handen Nursery, Manor Lane, Lee.

NOTICE. AN EMPLOYMENT REGISTRY DEPARTMENT IS CONDUCTED IN CONNEXION WITH THE "GARDENERS' MAGAZINE," AND THE CHARGE FOR AN ADVERTISEMENT INCLUDES A FREE ENTRY ON THE REGISTER FOR ONE MONTH. IF NOT SUITED AT THE END OF THAT TIME, AND IT IS DESIRED THAT A NAME SHOULD REMAIN, IT WILL BE CONTINUED FOR A FURTHER PERIOD UPON RECEIPT OF A REQUEST. IMMEDIATE NOTICE MUST BE GIVEN WHEN AN ENGAGEMENT IS SECURED.

A List of Gardeners on the Register will be supplied upon application to the Publishers if a stamped envelope is forwarded, addressed 148 and 149, Aldersgate Street, London, E.C.

NEW WHITE PINK "ALBINO" (LAMB'S).

Award of Merit R.H.S. June 15th, 1897.

The best white pink ever sent out, large size, full flower, smooth petal, seldom splits, very fragrant, more resembles a choice white Carnation than a pink. Plants 6d. each. Duchess of Portland, Carnation awarded XXX Chiswick trial, the highest award given, 9d. each, both true from the raiser (Lamb). Other varieties 6s. 6d. or 10s. 6d. per doz. Long spurred Aquilegias 2s. 6d., 4s., or 6s. per dozen. Cash with order.

J. LAMB, F.R.H.S., Burton Joyce, Notts.

NEW TWINE NETTING, 2 yds. wide, 3d. per yd.; 4 yds. wide, 6d. per yd. 1 inch mesh Tanned Netting, 2 yds. wide, 1d. per yd., 8s. 100 yds.; 4 yds. wide, 16s. per 100 yds. Suitable for seed-beds and lawn tennis courts. All kinds of nets made to order. Established 50 years.—W. CULLINGFORD, 177, Markhouse Road, Walthamstow.

VIOLETS.—Enormous stock, especially Princess of Wales, California, Amiral Avellan, Lady Hume Campbell, Swanley White. Quotations given for thirty varieties in stock.

MANAGERS, Hood Gardens, Totnes.

GREENHOUSES from £3 8s. VINERIES, conservatories, well-made frames, painted or glazed, from 21s.; illustrated price lists free. Maker to H.M. the Queen and H.R.H. the Prince of Wales.

1898 FORBES' CATALOGUE 1898

(over 150 pages—nearly 150 illustrations) of

FLORIST'S FLOWERS and HARDY BORDER PLANTS

is got up REGARDLESS of TROUBLE or EXPENSE, with the result that it is by UNANIMOUS CONSENT pronounced the most COMPREHENSIVE, most ACCURATE, most RELIABLE, most COMPLETE, and BEST EXTANT.

It gives full and ACCURATE DESCRIPTIONS of everything in the way of FLORIST'S FLOWERS, also COLOUR, HEIGHT, TIME of FLOWERING, and PRICE of all the best HARDY BORDER PLANTS, together with their ENGLISH or COMMON NAMES, and a mass of other VALUABLE INFORMATION that cannot be had elsewhere.

It is, in fact, a veritable REFERENCE-BOOK, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. Free on application.

PURE

GRASS SEEDS

Produce Beautiful Smooth Lawns, Tennis Lawns, Cricket and Croquet Grounds.

The following Mixtures of Grass Seeds are all thoroughly cleaned, and cannot fail to give the greatest satisfaction. There are neither Clover or Coarse Grasses in "**Our Mixture of Grasses.**" The seed is sold by weight, being the only correct method of estimating quantity needed for a given space:—

BARR'S "THAMES EMBANKMENT" GRASS SEEDS, for Parks.—A special mixture, which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1s. 3d.; per 10 lb., 11s. 6d.; per 20 lb., 21s.

BARR'S "STANDARD" GRASS SEEDS, for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1s. 6d.; per 10 lb., 13s. 6d.; per 20 lb., 25s.

BARR'S NEW MIXTURE OF DWARF GRASSES, for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an *extra fine velvety turf*, and saving labour in not requiring frequent mowing. Per lb., 2s.; per 10 lb., [illegible] per 20 lb., 37s.

BARR'S SEED GUIDE contains a Descriptive List of the best Vegetables and most beautiful Flowers, *Free on application.*

NOTES OF THE WEEK.

NATIONAL CHRYSANTHEMUM SOCIETY.

HALF-AN-HOUR or so before midnight on Monday the adjourned annual meeting of the National Chrysanthemum Society was brought to a close, and although the members who formed part of this memorable gathering must have been wearied by the discussion, which had proceeded with but one slight break for five and a half hours, the majority conld hardly have failed to experience a sense of satisfaction that the whole of the business had been disposed of. The first adjournment was, under the circumstances, inevitable, but a second would have been highly undesirable, for not only is it necessary the schedule should now be issued; but it is desirable the controversy should not be further continued. The results of the action of those members who are desirous that the affairs of the society should be conducted on business lines will be regarded as satisfactory or otherwise according to the standpoint from which they are judged; but we have overwhelming evidence that they have given much satisfaction to the majority of the members. More might possibly have been accomplished with advantage, but sufficient has been done to place the society on a more satisfactory basis than at any previous period in its history. The air has been cleared, the members have shown that they are determined the committee should exercise the powers vested in them, and the members of that body have at last become alive to the necessity of accepting their responsibilities. The action that was taken with a view to enable the members to know exactly the financial position of the society at the present time was fully justified by the events. The report and balance-sheet were referred back at the first meeting with instructions to the committee to prepare a proper balance-sheet, to prepare an estimate of the receipts and expenditure for the current year, and to report on the advisability of reducing the number of shows or the expenses of those which had been arranged. These instructions were carried out, and the revised financial statement presented to the members showed that it had been necessary to draw from the reserve fund nearly £50 to pay off outstanding liabilities, and that the estimated expenditure exceeded the estimated receipts by £48. The committee wisely recommended the reduction of the expenditure by about £70. The meeting accepted the recommendation; and, instead of indulging in a speculation as to what would have have happened at no distant date had no check been imposed upon the policy that obtained, we will consent ourselves with saying that the society is now quite sound financially, and that there is no reason why it should not build up a reserve fund proportionate to the position of the society. The lateness of the hour at which the questions relating to the place of holding the exhibitions was reached, prevented them being discussed at any considerable length; but we are pleased to say that they were considered in a business-like spirit, and in the result a resolution was passed instructing the committee to consider them, and report to a general meeting of members to be held in November next. If this be done, the members will be in a position to discuss the matter with profit to the society, and come to a decision on proper data. Whatever may be the outcome of the inquiry which the committee has been instructed to make, we have no doubt whatever that the beneficial effect of the reforms that have been made will be felt long before the date fixed for the meeting, at which the results are to be presented to the members.

SAVING THE PEACH CROP.

ONE of the chief difficulties in the outdoor culture of the peach in the United Kingdom is unquestionably the effective protection of the flowers and young fruits from spring frosts, and as this difficulty necessarily arises from the early period of the year in which the trees bloom, methods of retarding the development of the flowers are deserving of careful attention. In this direction numerous experiments have been made in this country, but in no instance with conspicuous success; unnailing the trees that the growth may not be unduly stimulated by the heat radiated from the wall, shading the trees in advance of the flowering season, and reversible walls, are perhaps the most important of the various methods of retarding the flower buds that have been suggested. The reversible walls were the invention of the late Mr. Shirley Hibberd, who devoted much time and money in perfecting the idea, and they consisted of panels of wood so made that they could be shifted from one side to the other of the trellis to which the trees were trained. During the winter the panels were placed on the south side of the trees to screen them from the stimulating effects of the sun, and there they remained until the trees were in bloom, when they were removed to the north side. Theoretically the idea was a capital one, but it was found impracticable to have walls of sufficient height to ensure success in peach culture because of the enormous weight of the panels. Shading with canvas blinds is seldom adopted, and attempts at retardation are now practically limited to unnailing the branches and keeping them away from the wall until the buds are beginning to expand. The risk of the precocious flowers being injured by frost is by no means confined to this country, but is equally great in much lower latitudes than ours. In the State of Missouri, for instance, where peach culture forms an important industry, the destruction of the blossom buds frequently inflicts a considerable loss upon the growers. It is therefore not surprising that the subject should have been investigated, and it would appear that the experiments conducted at the agricultural experiment station at Colombia have given results of considerable practical value. Missouri lies in nearly the same latitude as the south of Spain, but, as a matter of course, is subject to the extremes of weather characteristic of a continental climate, and has a lower temperature than is experienced in England. The injury done to the fruit buds in Missouri is usually due to the effects of frost upon them after the buds have been stimulated into growth by warm weather during the winter and early in the spring. The premature development of the buds is due to the warmth the buds receive, and is practically independent of the activity of the roots, as proved by the fact that it may occur on warm sunny days, while the ground is frozen to a considerable depth. The flower buds of peach trees are well able to withstand the effects of from ten to twenty degrees below zero, provided they are dormant; on the other hand, a frost with the thermometer at zero will kill buds that have, under the influence of warm weather, previously commenced to swell. Shading the trees with board sheds, and whitening them to prevent their absorbing too much heat, was tried at Colombia with good effect, and of the two the first-named method was the most effective, and it was found that the use of these board sheds enabled the peach buds to pass uninjured through the winter, when 80 per cent. of those unprotected were killed. Trees thus protected bloomed later, continued in flower for a longer period, and set their fruit more freely; but the protection is necessarily much too costly to be used other than on a large scale.

Garden Roses formed the subject of a lecture given by Mr. George Gordon, V.M.H., before the members of the Brighton Horticultural Society on the 17th inst. The meeting was held in the Oddfellows' Hall, with Mr. Balchin in the chair; and, judging from the attendance, much interest is evinced in the district in roses specially adapted for the embellishment of the garden. Mr. Gordon, after a brief reference to the popularity of the rose in ancient and modern times, the favour with which the flower has in all times been held by the poets, its mythological associations and the development of the several sections, proceeded to speak of the practical aspects of rose culture. Until within a comparatively recent period, it was pointed out, but scant encouragement was given at the exhibitions to roses that did not conform to the properties formulated by the florists, with the result that undue preference had been given to form in estimating the value of varieties. As the result of the recent expansion in the policy of the National Rose Society roses of special value for enhancing the attractions of the garden were now to be seen at the exhibitions, and visitors were surprised by the wondrous beauty of many varieties that were practically unknown. Mr. Gordon said that it was essential the standard of excellence should be maintained, and suggested that varieties in which high quality was combined with attractive colouring and freedom and continuity of flowering should have the preference. The continuous production of flowers was spoken as one of the most important attributes of roses grown for garden decoration and the supply of cut flowers, and the utility of the hybrid teas, teas and chinas was pointed out. It was suggested that only those hybrid perpetuals should be planted that bloomed throughout the summer and autumn, and that there should be a large extension in the planting of the hybrid teas and teas, more especially the latter, which can be grown with so much success in the southern counties. Good cultivation was essential to the full enjoyment of roses in the garden, and the several details essential to success were briefly described, and some of the more desirable varieties mentioned.

N.C.S. Exhibitions.—At the adjourned annual meeting of N.C.S., on Monday, the following resolution, moved by Mr. Moorman, was passed unanimously: "That a sub-committee of five members (exclusive of *ex-officio* members) be appointed to inquire (*a*) what places can be obtained for holding our future exhibitions either by a subsidy as now or in reliance on our own resources to proceed on independent lines; (*b*) to closely examine the whole question of minor shows with the object of ascertaining their advantages or otherwise to the society; (*c*) to fully consider the question of selling the floor space, and to report the result of their investigations to the general committee, who shall formulate such recommendations to a general meeting of members to be held on the evening of the first day of the November exhibition, and that no future fixtures be made before this date."

National Auricula Society.—We are pleased to learn from the report of the committee that the past year was the most successful for a long time past. There was, we are informed, a large accession of new members, and the financial statement shows that the balance in hand, although not so large as the friends of the society could wish, was materially increased. Last year the date of the exhibition was too early to admit of many of the northern growers taking part in the competition, and this year the show will be held a fortnight later (April 26), and, as usual, in conjunction with the R.H.S. meeting at Westminster.

Two and Three-Spathed Arums.—Mrs. Richards, of Westridge, near Ryde, forwarded to R.H.S. two stems, one with two spathes, the other with three, both from the same plant. They were very finely developed examples, and it was, in the opinion of the Scientific Committee, reasonable to expect such might prove constant. In the opinion of that body a permanent form with two or more spathes would be very desirable, but we regard it as undesirable, for the single spathes are far more elegant and beautiful than are monstrosities with several spathes crowded on one scape.

Chrysanthemum Exhibitions at Kingston, held annually during the past twenty-one years, have in a most marked manner assisted to bring the favourite autumn flower to the state of perfection in which we now know it. For very many years the Kingston and Surbiton Chrysanthemum Society held magnificent displays, and the prizes offered attracted the best growers in the kingdom; of late, however, the society has not been so well supported as of yore, and there was a danger of its collapse. Despair did not, however, enter into the composition of the commitee, and the members have bravely stuck to their work, so that now the whole of the liabilities have been discharged, with the exception of what is due to the collector and assistant secretary, who voluntarily offered to let that stand over. It is satisfactory to find that last year's subscriptions exceeded in amount the sum received in 1896, and had the takings at the door come up to the average, with a small reduction *pro rata* from the prize money (which is provided for in the rules), the accounts would have stood differently. As it is, the committee are determined to make an effort to wipe off the debt due to the collector, and are encouraged therein by the knowledge that the society has passed through critical periods more than once in its existence of twenty-one years. It has been definitely fixed to hold a show on November 1 and 2 next in the Drill Hall.

Horticultural and Forestry Education in Edinburgh.—The courses of instruction which have now for some years been in progress under the system instituted by Professor J. Bayley Balfour, the Regius Keeper of the Royal Botanic Garden, Edinburgh, is still as popular as at its first inauguration. The numerous subjects taken up by well-known specialists are made as complete as possible, and the benefit to the young men attending is apparent to all. The subject in progress now is "Landscape Gardening," being a course of five lectures by Henry E. Milner, Esq., A.M.I.E.E., F.L.S., V.M.H., &c., who lectures on consecutive evenings during the week, commencing on Monday, 21st inst. For the commencing lecture the syllabus shows the manner of dealing with the course: Introduction. The Development of Landscape Gardening. Enunciation of General Principles. The second leads up to the Selection of the Site. The Approach, The Terrace, and the Kitchen Garden. Third—Drainage Water. Structures, including Steps, walks, bridges, &c. The fourth takes up the Formation of the Ground, and Planting, and the last gives the wide subject of Design. The lectures, as are well known, are given in Botanic Garden, and these lectures are thrown open to the public through the courtesy of the Regius Keeper. The lecture on Monday was attended by a large number of persons interested, and a very instructive and pleasant history of the early styles of gardening were noticed by the lecturer from the earliest records down to the present century, concluding with a brief review of the value of the judicious uses of water, style of planting in the immediate vicinity of the house, and the uses of colour in the idea of promoting imaginative distances. The more practical points to be brought out will be brought out in the succeeding lectures, as will be apparent by a glance at the items upon the syllabus.

Mr. W. Bull's Orchid Sale, which takes place next week at the Ashburnham Road Nurseries, Chelsea, should prove a great attraction to those interested in this remarkable race of plants. The collection is extensive, and consists of fine, vigorous stuff; it includes most species with many notable varieties, too numerous to name, and its sale affords the enterprising orchid buyer an opportunity, not often met with, of obtaining a bargain worth securing. The sale will commence on Thursday next, the 28th inst., and be continued until the 31st inst., inclusive.

Highgate Chrysanthemum Society is extending its range of work, and it will be of some interest to watch the development of the new departure it has made. The other day we had an intimation to the effect that it had ceased to be affiliated with the National Chrysanthemum Society, and that it had decided to have its own certificates and medals, and now we are informed that it has appointed a Floral Committee and that "all persons, whether members of the society or not, are invited to exhibit new varieties of chrysanthemums at the meetings" of that body. The regulations have been drawn up on similar lines to those of the National Chrysanthemum Society, and the members are Mr. T. Bevan, Mr. J. Brooks, Mr. J. Brooks, jun., Mr. F. W. Birt, Mr. F. J. Matthews, and Mr. T. L. Turk, with the president (Mr. C. F. Cory Wright), the treasurer (Mr. J. McKershar), and the secretary (Mr. E. W. Boyce), the first-named gentleman being, it is interesting to observe, the chairman of the N.C.S. Floral Committee. It is proposed to hold three meetings during the chrysanthemum season, and the dates arranged are October 31 and November 8 and 14. Considering that ample opportunities are afforded in the metropolis for determining the merits of new chrysanthemums by bodies whose decisions command respect throughout the United Kingdom, the setting up of a third certificating body in London appears to us to be quite unnecessary.

Cyprus Diseased.—A specimen received by R.H.S. from Dr. Church, having the bark split and detached and infested with fungi, was forwarded to Kew for further examination. The following report was received: "Cupressus dolabrata.—This is a typical example of bark-scorching, the cortex being first killed by exposure to the sun's rays, afterwards splits and forms sun cracks, and finally separates from the wood. The fungus present—Corticium lacteus, *Fries*—is simply saprophytic on the dead parts."

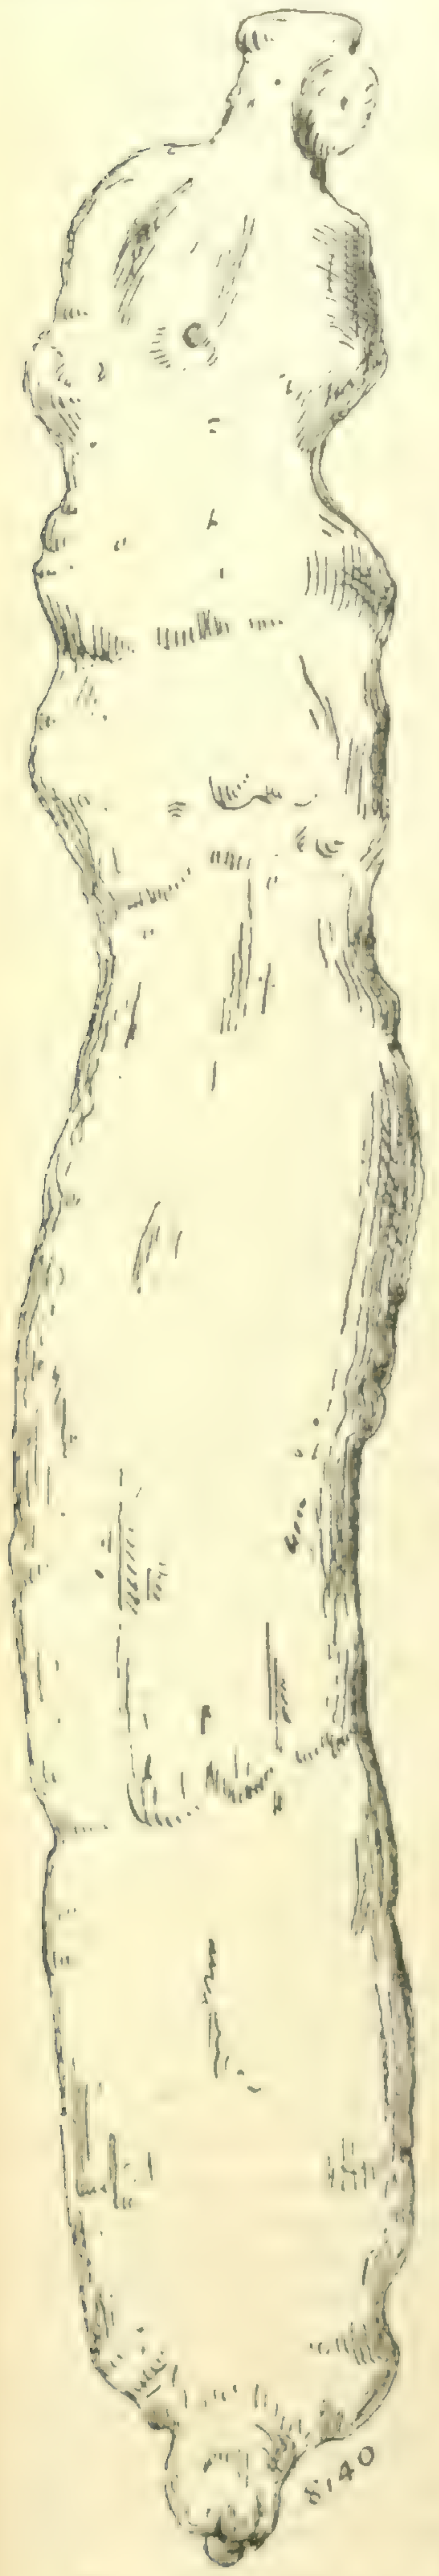
National Carnation and Picotee Society.—This society received a slight check last year, but it is financially so strong that the slight diminution in the balance in hand in no way interferes with the maintenance of its vigorous policy. Last year the exhibition was held in the gardens of the Royal Botanic Society, and the attendance was less than the committee "could have wished," and the flowers, owing to the untoward season, below the average. This year the exhibition will be held at the Crystal Palace on July 20. During last year there was an accession of seventy-eight new members, making a total of three hundred and fifty, and we are glad to observe that while membership may be obtained by the annual payment of five shillings, but few take advantage of it, with the result that the subscriptions of the above-mentioned number of members amounted last year to £236 6s. 6d. The classes for undressed blooms are continued, and the conditions for exhibiting in these classes have been altered, and they can now be exhibited either in boxes, bottles, or glasses.

Sprouting Broccoli.—A remarkable specimen was received the other day by the Scientific Committee of R.H.S. from Mr. W. P. Wright, Willesborough, Ashford, Kent, from the central and much-enlarged stem of which a large number of good-sized lateral shoots had appeared. It was suggested that if it be capable of being "fixed," it would probably prove a valuable acquisition.

The Sheffield Chrysanthemum Society does not forget the social side of life while it is engaged at the sterner business of advancing the interests of horticulturists in general and chrysanthemum growers in particular. It recently held a concert and ball at the Cambridge Hall, and the affair was well patronised; for as this, with the exception of the annual exhibition, is the only opportunity the ladies have of meeting with the members; there was a very large attendance. It pays at Sheffield to cater for the fair as well as the sterner sex.

NEW ARTICHOKE SYON LONG WHITE.

MANY and long have been the discussions held at various times upon the subject of artificial selection as practised by the horticulturist and agriculturist. In one sense artificial selection is akin to natural selection, inasmuch as it results in a survival of the fittest—the fittest for the purpose in view. In maintaining true stocks of their specialities our nurserymen and seedsmen have recourse to the most rigid selection, for unless this were done there would be more or less reversion to the original types. This selection entails a large expenditure of time and money, but of course it pays in the end, both the seller and the buyer. In the case of root crops, the process of selection is carried on, year by year, by those who have reputations at stake; but here the intervening and rejuvenating process is brought about by seed sowing. Some potatos, however, have been produced by the selection of tubers until a variety distinct from the original has been fixed. Seedlings are, in the case of potatos, most in vogue because of their vigour. With the tuberous rooted or Jerusalem artichoke (*Helianthus tuberosus*), there is very little opportunity, in this country at least, for either increase or differentiation by means of seedlings, as this seldom flowers and still more rarely seeds in the United Kingdom. Propagation has, however, been provided for by means of underground and swollen stems, generally known as tubers, which form the vegetable so dear to many. Until recent years little selection had taken place among artichokes, and the crop was usually relegated to some out-of-the-way, overshadowed part of the garden. In fact, the artichoke and horseradish were grown where nothing would succeed, and received but scant attention.



SYON LONG WHITE ARTICHOKE.

Two firms have taken in hand the improvement of artichoke tubers, with the result that two white varieties have been introducted to cultivation, and have become popular. One of these, Sutton's White, has fine round tubers, with white skin, the other, Vilmorin's White, has tubers of decidedly elongated shape. From the year of its introduction to commerce the first-named was cultivated at the Syon Gardens by Mr. George Wythes, and by growing the crop in an open position, and on ground that had been well manured for the previous crop, fine tubers resulted. Then, by careful selection, rounder tubers were produced, and in a few years a potato-like type, with shallow eyes, was fixed, and proved a material advance on the original form. The elongated artichoke, known as Vilmorin's White, was similarly cultivated, but instead of selecting from round tubers, the inclination of the variety to produce elongated tubers was assisted, and only those tubers showing great length and substance were selected each season for planting. After several years of such rigid selection Mr. Wythes has obtained a remarkably distinct artichoke, white skinned and white fleshed, often measuring twelve inches in length, and of good thickness. This new variety, Syon Long White, yields abundant crops, and the tubers are almost devoid of those warty excresences so plentiful on the old artichoke, and which necessitated thick peeling, and consequent waste, to ensure a shapely appearance when upon the table. The eyes are also very superficial, and when cooked the tubers have a distinct and pleasant flavour. The very largest may be cooked and served like salsify, when they are much appreciated; or they may be peeled and cut into two or more pieces if preferred. Mr. Wythes states that this new form is as vigorous as could be desired, and as hardy as the old dark-skinned type. Consequently it is best to leave the tubers in the ground until needed for use, placing some dry litter over the crop, or a portion of it, in the winter, to prevent hard frosts causing any difficulty in lifting. The accompanying illustration represents Syon Long White artichoke on a much reduced scale, but it afford our readers an opportunity of appreciating what Mr. Wythes has accomplished as the result of several years of careful selection towards a particular ideal. The variety now comes true every year, so that it is what florists would termed "fixed." Mr. Wythes has in other directions done excellent work in the improvement of vegetables, but in no sense have the results been associated with a greater degree of interest than with the improvement of the Jerusalem artichoke.

MICHAELMAS DAISIES.

I WAS rather surprised to read in a recent issue that "Lux" does not approve of the extended cultivation of early-flowering chrysanthemums, thinking that these will not find favour with the public. I was not thinking so much of the general public when penning my few notes as of gardeners in a similar position to the celebrated "Peter" and myself, and by sending to our editor early in the year I thought it would give those who might be induced to grow them an opportunity to obtain what I know to be really good and useful varieties. I must apologise for having "worried" even one of the readers of the GARDENERS' MAGAZINE, and particularly so distinguished a one, but I really cannot conceive a gentleman with such truly enthusiastic gardening proclivities as "Lux," having once seen well-grown bushes of Ivy Stark and Mdlle. Marie Masse, for instance, in their September beauty, being disposed to bestow anything but praise on their charm and usefulness in the garden. Perhaps "Peter" has not yet grown any but the dull-coloured and inartistic varieties for his master, and so opportunities have been lacking for the appreciation of those which I feel justified in recommending for either large or small gardens. I shall be very pleased, if I may be allowed, to post just a few rooted cuttings to our editor for him to forward to the "Luxian" garden, where, I am confident, they will flourish, and please also, and by their appeals next September for increased cultivation they will restore the good understanding which, I am sorry to learn, is slightly strained between us at present.

I am quite in accord with all the good that may be said of the Michaelmas daisies, and it was rather a coincidence that we were planting a border of some eighty varieties on the same day which gave the invite from "Lux" in the MAGAZINE, to urge the claims of these useful and charming flowers. These perennial asters are so easily grown and readily increased that for a few shillings a splendid selection may be purchased and grown by anyone who has room for autumn flowers. The height of the plants varies from one foot to six or seven feet, according to the variety and condition of the soil in which they are planted. The habit of growth, too, is varied; in some it is extremely light, spreading, and graceful; in others, close and compact, forming dense heads, while some are quite erect and others pendulous.

They form quite an interesting feature in a garden if given a border entirely to themselves, where a collection of varieties may be planted in informal arrangement and their respective merits easily compared. In such a border the aim should not be to obtain as much uniformity as possible by planting all the tall varieties in a back row and the dwarf ones in the front, but rather allow the most dense in habit of the tall ones to occupy the back of the border, and the very light and graceful tall ones, like Aster lævis Chapmani, may be planted well forward amongst less tall ones. Then, such a fine spreading head as Coombe Fishacre makes must not be too closely surrounded by other plants, as half the effect of this is destroyed by anything like crowding. The colours are not difficult to deal with, as they are mostly shades of lavender and blue with some white and one or too rosy coloured sorts. In mixed borders of herbaceous plants they help to keep up a display until late autumn, and for cutting nothing is so useful for large vases, as the long, branching stems need no special arrangement; simply cut two or three and place them in the vase just as they come from the plants, and nothing can improve them. The employment of the best and most showy varieties in large groups amongst shrubs is, perhaps, the most charming of all arrangements, especially for distant effect. In large gardens where many positions can be found for planting in this way, it is, perhaps, best to avoid repeating a variety, but to have only one large group of each of the best. The effect of a group of some two dozen or more plants of Ella disposed amongst thinly planted shrubs, or planted *en masse* in the foreground of a shrubbery at the end of some natural vista is most beautiful, and helps to sustain the interest of the garden when most of the border plants are past their best. It is important, in order to ensure the best results, to plant where a sheltering background lends its influence, because the colours are mostly pale, and need a dark contrast to emphasise them; if planted in the open much of their charm is lost.

Annual replanting and division, with a liberal dressing of manure to the soil, will be found the most satisfactory management. If the plants are not divided, the numerous growths at the base must be well thinned, particularly so in branching, and much-spreading sorts or too crowded a growth means less vigour and poor display. One very important feature is the tying up of the plants to stakes; the whole beauty of the plants is frequently destroyed through the bundling together of the growths in tying. It must be the aim to preserve the free and natural habit, and this may easily be done by just looping each of the main branches to a stout stake, which may be entirely hidden by the plant. A good selection of varieties is included in the following, and it will suffice to give just the names. Ella and Harper Crewe are about six feet high; Coombe Fishacre, A. Chapmani, A. cordifolius Diana, A. cordifolius elegans, Maia, Apollo, Snowflake, A. Shorti, A. versicolor, and A. vimeneus, each between four and five feet; A. acris, A. amellus, A. densus, A. lævigatus, A. ericoides elegans, and A. vimineus nana are less than three feet in height. These by no means exhaust all the good ones, but the list embraces the best, and also those named give a succession of blossom from early September until the end of October. Plants are easily raised from seeds, and a very large proportion of good types may be obtained from carefully saved seed. I saw a large bed of seedlings from A. amellus in Mr. Davis's nursery at Framfield last autumn, and considerable variation was noticeable both in colour and time of flowering. Cuttings rooted in spring make capital dwarf plants, and by this means, when it is desirable, the height of various sorts may be reduced to provide any special feature in the flower garden, though, generally speaking, plants allowed to grow naturally will produce the best effect.

Trent Park, Barnet. W. H. LEES.

FRAGRANT ROSES.

THE title of this article is reminiscent of the odorous atmosphere of summer, which, now that our much-loved roses are beginning to unfold their luminous, and in many instances richly fragrant, leaves, does not seem so far away. In the meantime the daffodil is filling our woods and gardens with its far-shining golden hues, and the auricula, fairest and most fragrant of the flowers of April (to be followed in due course by the lily of the valley), will soon be here. Many, indeed, are the floral fascinations that lie between us and the first efflorescence of the rose.

I have always regarded the want of fragrance in certain roses, otherwise of great attractiveness, as a very serious limitation; and I have been gratified to discover from one of his most recent and most interesting contributions on rose cultivation and selection that the Rev. H. D'ombrain takes a very similar view. Such roses, for example, as Baroness Rothschild, Spenser, and Her Majesty, however commanding in their dimensions, lose a great deal in the estimation of thousands by their want of this attribute, which is so powerful in its influence as to cover a whole multitude of weaknesses wherever it appears. To my mind it is almost more valuable than colour in a flower. The Oriental poppy is lustrous in aspect and impressive in size; but who would prefer it to the sweet-scented violet, hiding itself, like humility, amid its all-enfolding leaves? Who, on the other hand, save an ardent exhibitor, would prefer a scentless flower of Her Majesty, however majestic, to an intensely fragrant bloom of La France? I entirely coincide with the strongly-expressed opinion of the venerable founder of the National Rose Society (which was not originated for the perpetual conservation of flowers without sweetness), that roses which have not the essential attribute of fragrance should be remorselessly relegated to oblivion. It is, nevertheless, much to be regretted that some of our finest dark crimson varieties which we cannot entirely dispense with, such, for example, as the famous Duke of Edinburgh and its numerous variations, have so little attractiveness in this special direction. Of these it may expressively be affirmed that their colour is their salvation. But, on the other hand, we could survive the absolute extinction of such scentless pale-pink varieties as those which I have indicated, so long as we possessed, and were proud of possessing, more decided pink roses of a widely different description, such as Mrs. Sharman Crawford, one of the finest creations of the Dicksons at Newtownards; Mrs. John Laing, and Madame Gabriel Luizet, of which the last-mentioned will not soon be superseded.

Nearly all of the hybrid perpetuals have fragrance; many of them, however, only to a limited extent. Among the sweetest of these are Marie Bauman, Beauty of Waltham, Crown Prince, and Captain Hayward, raised by the late Mr. Henry Bennet, which is, perhaps, from this special point of view, the most attractive of them all. There are many other roses belonging to this class which might also be enumerated and highly eulogised, but this is not essential. Mr. Cranston's Crimson Bedder has in a former article on a kindred subject been much commended as a beautifully coloured and richly fragrant rose. Most of the Chinas and polyanthas, moss and Provence varieties possess a delicate aroma; among them may be mentioned Madame Laurette Messimy, of comparatively recent introduction; Queen Mab and Duke of York, raised by Mr. William Paul; Cramoisie Superieure; Hermosa, an improvement in fulness and form on the "Old Monthly" rose; Anna Marie de Montravel, sweetest in my estimation of the dwarf polyanthas, which has an odour peculiarly its own; the pink and white Provence; Blanche Moreau, finest of all the moss roses, and the eminently beautiful Crested Moss. Very fragrant alike in flower and foliage are the Austrian, Persian, and Penzance briars, and the latter are fascinating long after they have ceased to bloom.

Nearly all the noisettes and teas have a fragrance which is at once delicate and refined. Among the former are L'Ideal, the venerable Lamarque, and the finest of this section, the superb Maréchal Niel, which, it is to be regretted, is not adapted by nature for effective garden cultivation. Of Cloth of Gold I cannot speak either from observation or experience, as I have never had the privilege of seeing it in bloom. The perfume of Gloire de Dijon is very pleasing; so also, as a natural consequence, is that of Belle Lyonnaise and the graceful Bouquet d'Or, whose nature is so amiable that it succeeds admirably in my garden on a wall with a northern aspect, where it is, necessarily, greatly exposed. I find it much hardier and much more reliable than Reve d'Or, which requires a very sunny situation, and usually has to grow to its full dimensions before it attempts anything in the floral direction. Aimée Vibert has no fragrance whatever, but the foliage is beautiful, and when it does bloom it produces a vast number of flowers. Of all tea roses, perhaps, the most attractively fragrant are Souvenir d'un Ami and Souvenir de S. A. Prince. Niphetos and Madame Bravy have an exquisite perfume, the latter particularly; while Catherine Mermet and her daughters, Bridesmaid, The Bride, and Muriel Grahame, have a fragrance of a very peculiar character, which has been compared, not without reason, to that of a ripe peach. The most odorous of the Bourbons are Acidale, Mrs. Paul, and Madame Isaac Pereire. Mrs. Paul was raised at Cheshunt in 1891, and is a variety of immense vigour, unique colour, a fragrance rivalling that of Viscountess Folkestone, and imposing dimensions. It has the habit of its parent, Madame Isaac Pereire, but in no other respect save that of strong growth and freedom of flowering can any other resemblance between those closely affiliated roses be found. The fragrance of Mrs. Paul is of an entirely different quality from that of the majestic rose from which it was derived. This is a phenomenon—if such it may be termed—remarkably rare.

The most fragrant of all roses are the hybrid teas, and of these the most attractive are La France, Caroline Testout, Duchess of Albany, Cheshunt Hybrid, Camoens, Augustine Guinoisseau, Viscountess Folkestone, Lady Mary Fitzwilliam, White Lady, and Princess May. Of these by far the richest in its perfume is the incomparable La France. I understand that its illustrious raiser, the late M. Guillot, did not know to what section this gracious rose belonged. I sometimes think it is, to some extent, of hybrid China extraction; but this is a matter of little importance so long as it possesses those splendid characteristics which have made it what it is—one of the grandest existing roses for exhibition, and one of the most effective for garden decoration.

DAVID R. WILLIAMSON.

APPLES AS ESPALIERS.

IT is an interesting and economical method of cultivation to grow apples as espaliers, and one which especially commends itself to the owners of small gardens. Espaliers when compared with bush and pyramid trees take up but a small amount of space, and this is a great desideratum with many. As a rule, room can be found for but few trees grown in bush or pyramidal form in gardens of modest pretensions, as they encroach too much on the area at disposal for vegetables. This difficulty may be overcome if espaliers are employed, as they not only economise space, but enable owners to grow a greater number of varieties in a given space. The best plan is to plant the trees by the side of the walks, and so form a kind of fence, which leaves the remainder of the ground at liberty for other purposes. If planted eighteen inches or two feet from the edge of the walk, the narrow border so formed in front can then be utilised for growing strawberries, or low-growing flowering plants, lettuces, parsley, or anything which will not interfere with or injure the roots of the trees. Even in gardens of large areas, where plenty of space is available, a few rows of espaliers are always useful, while they certainly are ornamental if planted where they can be seen to advantage.

Espaliers are often planted to screen off the vegetable quarters, and in this case the trees should stand back quite a yard from the edge of the path. The border formed in front of the trees, as a result of this arrangement, comes in useful for strawberry growing, and a host of other things which it is not necessary to mention. This same form of tree can also be used to form a boundary line between flower borders and the vegetable quarters, when herbaceous and other flowering plants have to be accommodated in the kitchen garden for affording quantities of cut flowers. The taller and rank-growing plants should be eschewed, unless an alley quite a yard wide can be left between the back row of plants and the trees. Another good way of utilising espaliers is to plant them so as to enclose blocks of span-roofed houses and pits, when the latter are built in a conspicuous part of the garden. The enclosure so formed makes a nice finish, while the trees offer not the slightest obstruction to the free passage of light. Convenient openings must, of course, be left so that the houses and pits may be readily approached. Again, in the case of a range of lean-to houses, it is far better to plant espaliers to form the boundary line to the vegetable quarters facing the range than to employ bushes or pyramids, as the latter very often give too much shade.

Regarding the cropping capabilities of the apple when grown in this way, the results are very satisfactory, and the fruits produced are, generally speaking, clear skinned and high coloured, the latter varying according to soil and locality. Some sorts are much better adapted for growing as espaliers than others, and in the list which will be given subsequently only those will be mentioned which succeed as such. For small gardens a selection can be made which will afford a supply from early September up till March or April. For this purpose Beauty of Bath, Worcester Pearmain, Ribston and Cox's Orange Pippins, Adams' Pearmain, Allen's Everlasting, Lord Grosvenor, Beauty of Kent, Warner's King, Golden Noble, Reinette du Canada, and Wellington are twelve [illegible] sorts. If only half the number is required, select numbers one, [illegible] seven, ten, and twelve. If a more extended list is wished for, King of the Pippins, Fearn's Pippin, Lewis's Incomparable, Golden Reinette, Pearson's Plate, Blenheim Pippin, Ecklinville, Lord Derby, [illegible] Tyler's Kernel, Sandringham, and Annie Elizabeth may be added, which brings the number up to twenty-four.

Suitable trellises on which to train the trees can be constructed of wooden posts and galvanised wire at a cheap rate. Iron standards are, of course, the most durable, but much more expensive. Stout oak and larch posts, with the lower portions creosoted, or charred, and then plunged while hot into gas tar, will endure for a good many years. The height of the trellis need not exceed five feet, or five feet six inches, and the wires should stand fifteen inches apart. Radisseurs, or straining bolts, should be fixed at one end of the trellis for the purpose of tightening the wires, both at the time of fixing and for future use, should any of the wires become slackened. As to distances, the trees may be planted from twelve feet to fifteen feet apart, according to space at disposal. When in bloom espaliers are easily protected from spring frosts, either by means of hurdles thatched with straw or bracken, or blinds of Frigi Domo, or similar material. In the latter case a few short stakes are required to keep the blinds from coming into contact with the trees. The hurdles should be stood close up to the trees with the top leaned against [illegible] the highest wire. In either case they act as a very efficient [illegible] protective agent.

Stoke Edith Gardens.

Yellow Ground Picotees.—Practical expression has been given by the Midland Carnation and Picotee Society to the suggestion made in these pages a few years since that separate classes should be provided for yellow-ground picotees possessing the requirements of the florist. In the schedule several classes are provided for them, with prizes more liberal than in the corresponding classes for white ground picotees and show carnations. It is stipulated in these classes that "Any bloom that has not a continuous picotee edge, or has more [illegible] colour on the yellow ground, will be disqualified; for example, [illegible] Gift, and such-like flowers will be admissible, but not such flowers as [illegible] Bail and Yellow Hammer."

VEGETABLES FOR EXHIBITION.

ONIONS.

THE onion (*Allium cepa*) is one of the most useful and largely cultivated vegetables in this country. At the same time it is not nearly so extensively grown as it should be, and when one considers the large quantities annually imported from Spain and other countries, it is indeed surprising that market gardeners and farmers at home do not turn their attention to the production of these bulbs on a larger scale. Almost any kind of land, when properly prepared, will grow onions well, but unquestionably the most suitable soil is a deep light loam, which will only require enriching and preparing during the winter months. When, however, one has to deal with less favourable mediums, such as stiff clay, or chalky and gravelly soil, more attention and care will have to be bestowed to produce satisfactory results. The onion is a deep-rooted plant, consequently merely digging over the ground and working in a little manure is not sufficient. In all cases the land ought to be thoroughly trenched, and heavily manured during the winter months. Onions require a long season of growth, and the sowing made early in the season gives by far the best results, as the bulbs may be properly matured and ripened before the summer is too far advanced. One often hears of onions keeping badly, and this is in nearly all cases due to bad harvesting. For ordinary summer crops the site should be selected during the autumn. Many people make their onion bed on the ground previously occupied by spring cabbage, a very good practice which I generally adopt myself. If alternated each year, that is onions following cabbage, and cabbage following onions, good results will ensue. On the first favourable occasion in early autumn, wheel on a thorough dressing of good farmyard manure (it is scarcely possible to give too much), and as soon as the ground is in a moderately dry state, the trenching should be done to a depth of not less than two feet six inches, breaking up the bottom thoroughly with a fork. Begin with a layer of the longest of the manure, and on this should be thrown the top spit, then a layer of the shortest of the manure should be added. No attempt should be made to break the soil to pieces, but the whole ought to be left in as rough and lumpy a state as possible, so that the frost and winds may penetrate it thoroughly. Leave in this way till early spring. As before stated, the seed should be sown early, say, from February 25 to not later than the end of the second week in March, if possible. At this season we are very much at the mercy of the weather, owing sometimes to prolonged frost and much wet, either of which may prevent the operation, especially so on heavy soil, but no chance ought to be missed after the first-mentioned date. A mixture of soot, wood ashes, and lime in equal proportions should be strewn over the bed; and on heavy soil, in addition to this, a thorough coating of road-grit will prove of much value. Fork over the bed to a depth of eight inches, breaking up the lumps as fine as possible, and leave it for three or four days; then proceed to prepare for seed sowing.

A short-toothed wooden rake should be used to make the bed as level as possible, and draw off any large stones or rubbish; next mark out the beds, the drills being from ten to twelve inches apart, a distance I recommend in all cases. Round the outside of the bed an eighteen-inch alley should be allowed, and one of fifteen inches at every eight feet of width. The drills should be drawn very shallow, after which sow fairly thick and evenly. Cover in the seed with the feet, walking down each row and pressing down the soil firmly on both sides, after which the beds should be trodden down firmly in the opposite direction, walking across the beds. The wooden rake should again be brought into use over the whole bed, after which finish neatly with an iron one. The beds should be left as even and fine as it is possible to make them, and a small rake may also be passed down the alleys. Good gardeners pride themselves on their onion bed, and well it looks when properly done. A quick free growth must be encouraged to ensure a good crop, so that immediately the young plants are above the ground and the rows can be seen, the Dutch hoe should be brought into use, and the soil stirred carefully between the drills. This should be done frequently, and the young plants should be lightly dusted with fresh soot weekly. As soon as large enough commence thinning and hand weeding. It is a great mistake to thin severely the first time, unless extra large bulbs are wanted, and these are more easily obtained by another method, which will be set forth later. As a rule, for all ordinary culinary purposes bulbs from the main sowing will be quite large enough, and when hard thinning is practised an attack of the onion fly will often play sad havoc with the crop. If thought to be too crowded, and all is going well, another thinning can be made at a later period. When the weather is showery, in addition to the application of soot, which is a capital stimulant, a light dressing of some good artificial manure should be given and stirred in with the Dutch hoe. I have found Smyth's fertiliser a good and safe manure for this purpose. Should the weather continue dry for any length of time, give good drenchings of water, using if possible that taken from the sewage tank. As soon as the growth appears to be complete the top should be carefully laid down with the hands, turning them all one way in a neat and business-like manner, and not knocking them down with a broom, as is frequently done. This latter practice is much to be deprecated, as the growths must necessarily be damaged by bruising, and any injury greatly impairs the keeping qualities. In about ten days or a fortnight the whole should be pulled up and laid in beds to finally ripen, where they should be turned over about every third day when the weather is dry. In about nine or ten days they ought to be ready for taking under cover, placing them thinly in an airy shed and turning once or twice before storing. No better way for keeping onions can be found than roping them and hanging them up in a cool shed. Failing this, lay thinly on shelves.

Aldenham House Gardens. E. BECKETT

CAMELLIAS AT WALTHAM CROSS.

IT is not exactly pleasant to reflect that the most beautiful of the flowering plants should be subject to the caprice of fashion, and that in consequence of a change in the trend of public taste that the camellias, with their wondrous beauty of leafage and flowers, should have for so long a period been relegated to the cold shade of neglect. Once the most popular of the hard-wooded plants that thrive in the conservatory, they so steadily declined in public favour that they have been practically banished from many trade collections, and their cultivation materially reduced in private gardens. Why there should have been so continuous an ebb in public favour is not easy to explain, or, indeed, to understand. The enormous increase in the cultivation of the chrysanthemum during the past twenty years has undoubtedly been one of the contributing causes, and it may be assumed that the winter-flowering carnations have proved formidable competitors for public favour. If the camellias were of use only for the production of flowers for personal adornment and home decoration in a cut state, their decline in popularity could be readily understood; but having regard to the fact that their value consists in their usefulness in enhancing the attractions of the conservatory and winter garden early in the year, it is surprising that these handsome shrubs should have suffered so severely from the competition to which they have been subjected.

Happily, the neglect of camellias has reached the bottom, and that once more the tide of public taste has begun to flow in their favour. We have full justification for the opinion we hold upon this point in the fact that there is a steadily increasing demand for camellias, and more particularly for large specimens. This we mention with considerable pleasure, not because we hold their shapely blooms and exquisite colouring in high estimation, but from our knowledge that we have no shrubs at home in the conservatory that can compare with them in attractiveness at this season of the year. As so well known to those who have kept themselves well acquainted with the various phases of horticulture, Messrs. William Paul and Son have throughout maintained their magnificent collection in its completeness, and unless we are much mistaken they are now obtaining an adequate reward and devotion to these beautiful shrubs. We have been acquainted with this collection for many years, but at no time have we heard any complaint as to the difficulty in disposing of the immense number of plants raised annually, but now we learn that the demand has of late so materially increased as to necessitate renewed activity in the maintenance of stock. The extent of the collection, and its richness in splendidly developed specimens has, no doubt, been an important factor, but we are disposed to attach greater importance to the fact that the whole of the stock is of home growth. Long before the decline in the popularity of the camellia, Messrs. W. Paul and Son recognised the superiority of home-raised plants over those of continental origin, and the practice which was then initiated has been continued until the present day, and with highly satisfactory results.

As we have explained in previous references to the camellias at Waltham Cross, the collection occupies a span-roof structure about one hundred and thirty feet in length and thirty feet in width, and includes an immense number of buxom bushes, ranging from five feet to over twenty feet in height. We have also spoken in high terms of the remarkable skill that is brought to bear upon the plants, and of their robust condition and the abundant production of flowers that have resulted from the practice adopted. But in no season in which we have have had an opportunity of seeing them have they presented a more satisfactory appearance, or gave a greater wealth of flowers, than the one through which we are now passing. The collection is unique, and of much value for the object lessons it affords upon points of practice and in the selection of varieties; and, with regard to the latter, it may be said that nowhere in the United Kingdom is so large a number of distinct and beautiful forms to be met with. Special attention has been devoted by the firm to the raising and introduction of new varieties, as well as to the growth of old ones, and the novelties now form a large and important group. Chief among the varieties raised at Waltham Cross are Beauty of Waltham, a distinct and beautiful variety, with good habit and finely-formed flowers of a pleasing flesh colour. Duchess of York, a charming camellia with bold rose cerise flowers and excellent foliage. Exquisite, a fine variety with large, handsome, rose-red flowers and good foliage, and The Duchess, a distinct variety, distinguished by the beauty of its rose-pink flowers and handsome foliage. Messrs. W. Paul and Son have also been successful in introducing a considerable number of beautiful camellias from Portugal, which not only have flowers of superb form, but foliage surpassing that of the majority of those of Italian origin. Bold, deeply-coloured leaves are hardly less necessary in a camellia than are handsome flowers, and those who are acquainted with the beautiful variety known as the Marchioness of Exeter will be gratified to learn that the Portuguese camellias in the collection are not less satisfactory in this respect. The eight varieties enumerated in the catalogue of the firm are all so good as to occasion some difficulty in determining their relative merits, with one exception, and that marks so decided an advance as to at once place it in premier position. This is José Marques Loureiro, which has the habit and the ample dark foliage of Marchioness of Exeter, and pure white flowers posssessing the characteristics of those of the Double White, but with rather more boldness. It is believed that it will eventually supersede the Double White, and there is full justification for the belief. Other Portuguese camellias of special value are Barao de Mogofores, bright rose, in the way of Reine des Fleurs, but of a softer shade of rose; Camillo Aureliano, rose-pink splashed with white; Duarte d'Oliverro, rich rose, very distinct; Horto Loureiro, flesh pink flaked with rose and crimson. Several of the Portuguese varieties were received through the Marquise Fronteira, Benifica, near Lisbon, who, when visiting the Waltham Cross Nurseries, was so charmed with the collection that he sent the firm a selection of the finest grown in Portuguese gardens.

The collection of older varieties contains many of remarkable beauty that are comparatively little known, while all the varieties with which the English cultivator is familiar are strongly represented. Of the self-coloured varieties that are remarkable for their distinctness and beauty, mention must be made of, as especially desirable in collections: Alba plena, pure white; Auguste Delfosse, red-crimson; Baron de Vriere, peach colour; Beali, crimson; Benneyi, bright red; Chandleri, crimson, very free; C. M. Hovey, scarlet-crimson, very fine; Conspicua, rose, semi-double, very free and desirable; Dionisia Poniatowski, white, very fine; Fatima, deep rose-red; Fimbriata, one of the most beautiful of the pure white varieties; Guillaume III., dark rose-red, large, superb form; La Constituzioni, rose-pink, large, fine shape; Marchioness of Exeter, glowing rose, fine habit, and large handsome flowers; Malhotiana, deep crimson, large and effective; Rafia, dark crimson; Rose de la Reine, rose-crimson; and Souvenir d'Emile Defresne, bright red. Conspicuous among the varieties with striped and blotched flowers, by reason of their attractiveness and high quality, were: Adelina Benvenuti, flesh flaked crimson, exceedingly beautiful; Countess of Derby, white, flaked rose; Donckelaari, crimson, flaked white; Countess of Orkney, white, flaked carmine; L'Avenir, rose, margined and striped white; Madame Ambroise Verschaffelt, white, flaked and spotted red; Princess Clothilde, white, striped with carmine, semi-double, and very effective; and Tricolor, flesh striped with crimson, semi-double.

The foregoing are mentioned as indicating a few that are specially suitable for small collections, but there are large numbers of other varieties that are of great beauty and deserving of the highest encomiums, as will be seen in the course of an inspection of the Waltham Cross collection.

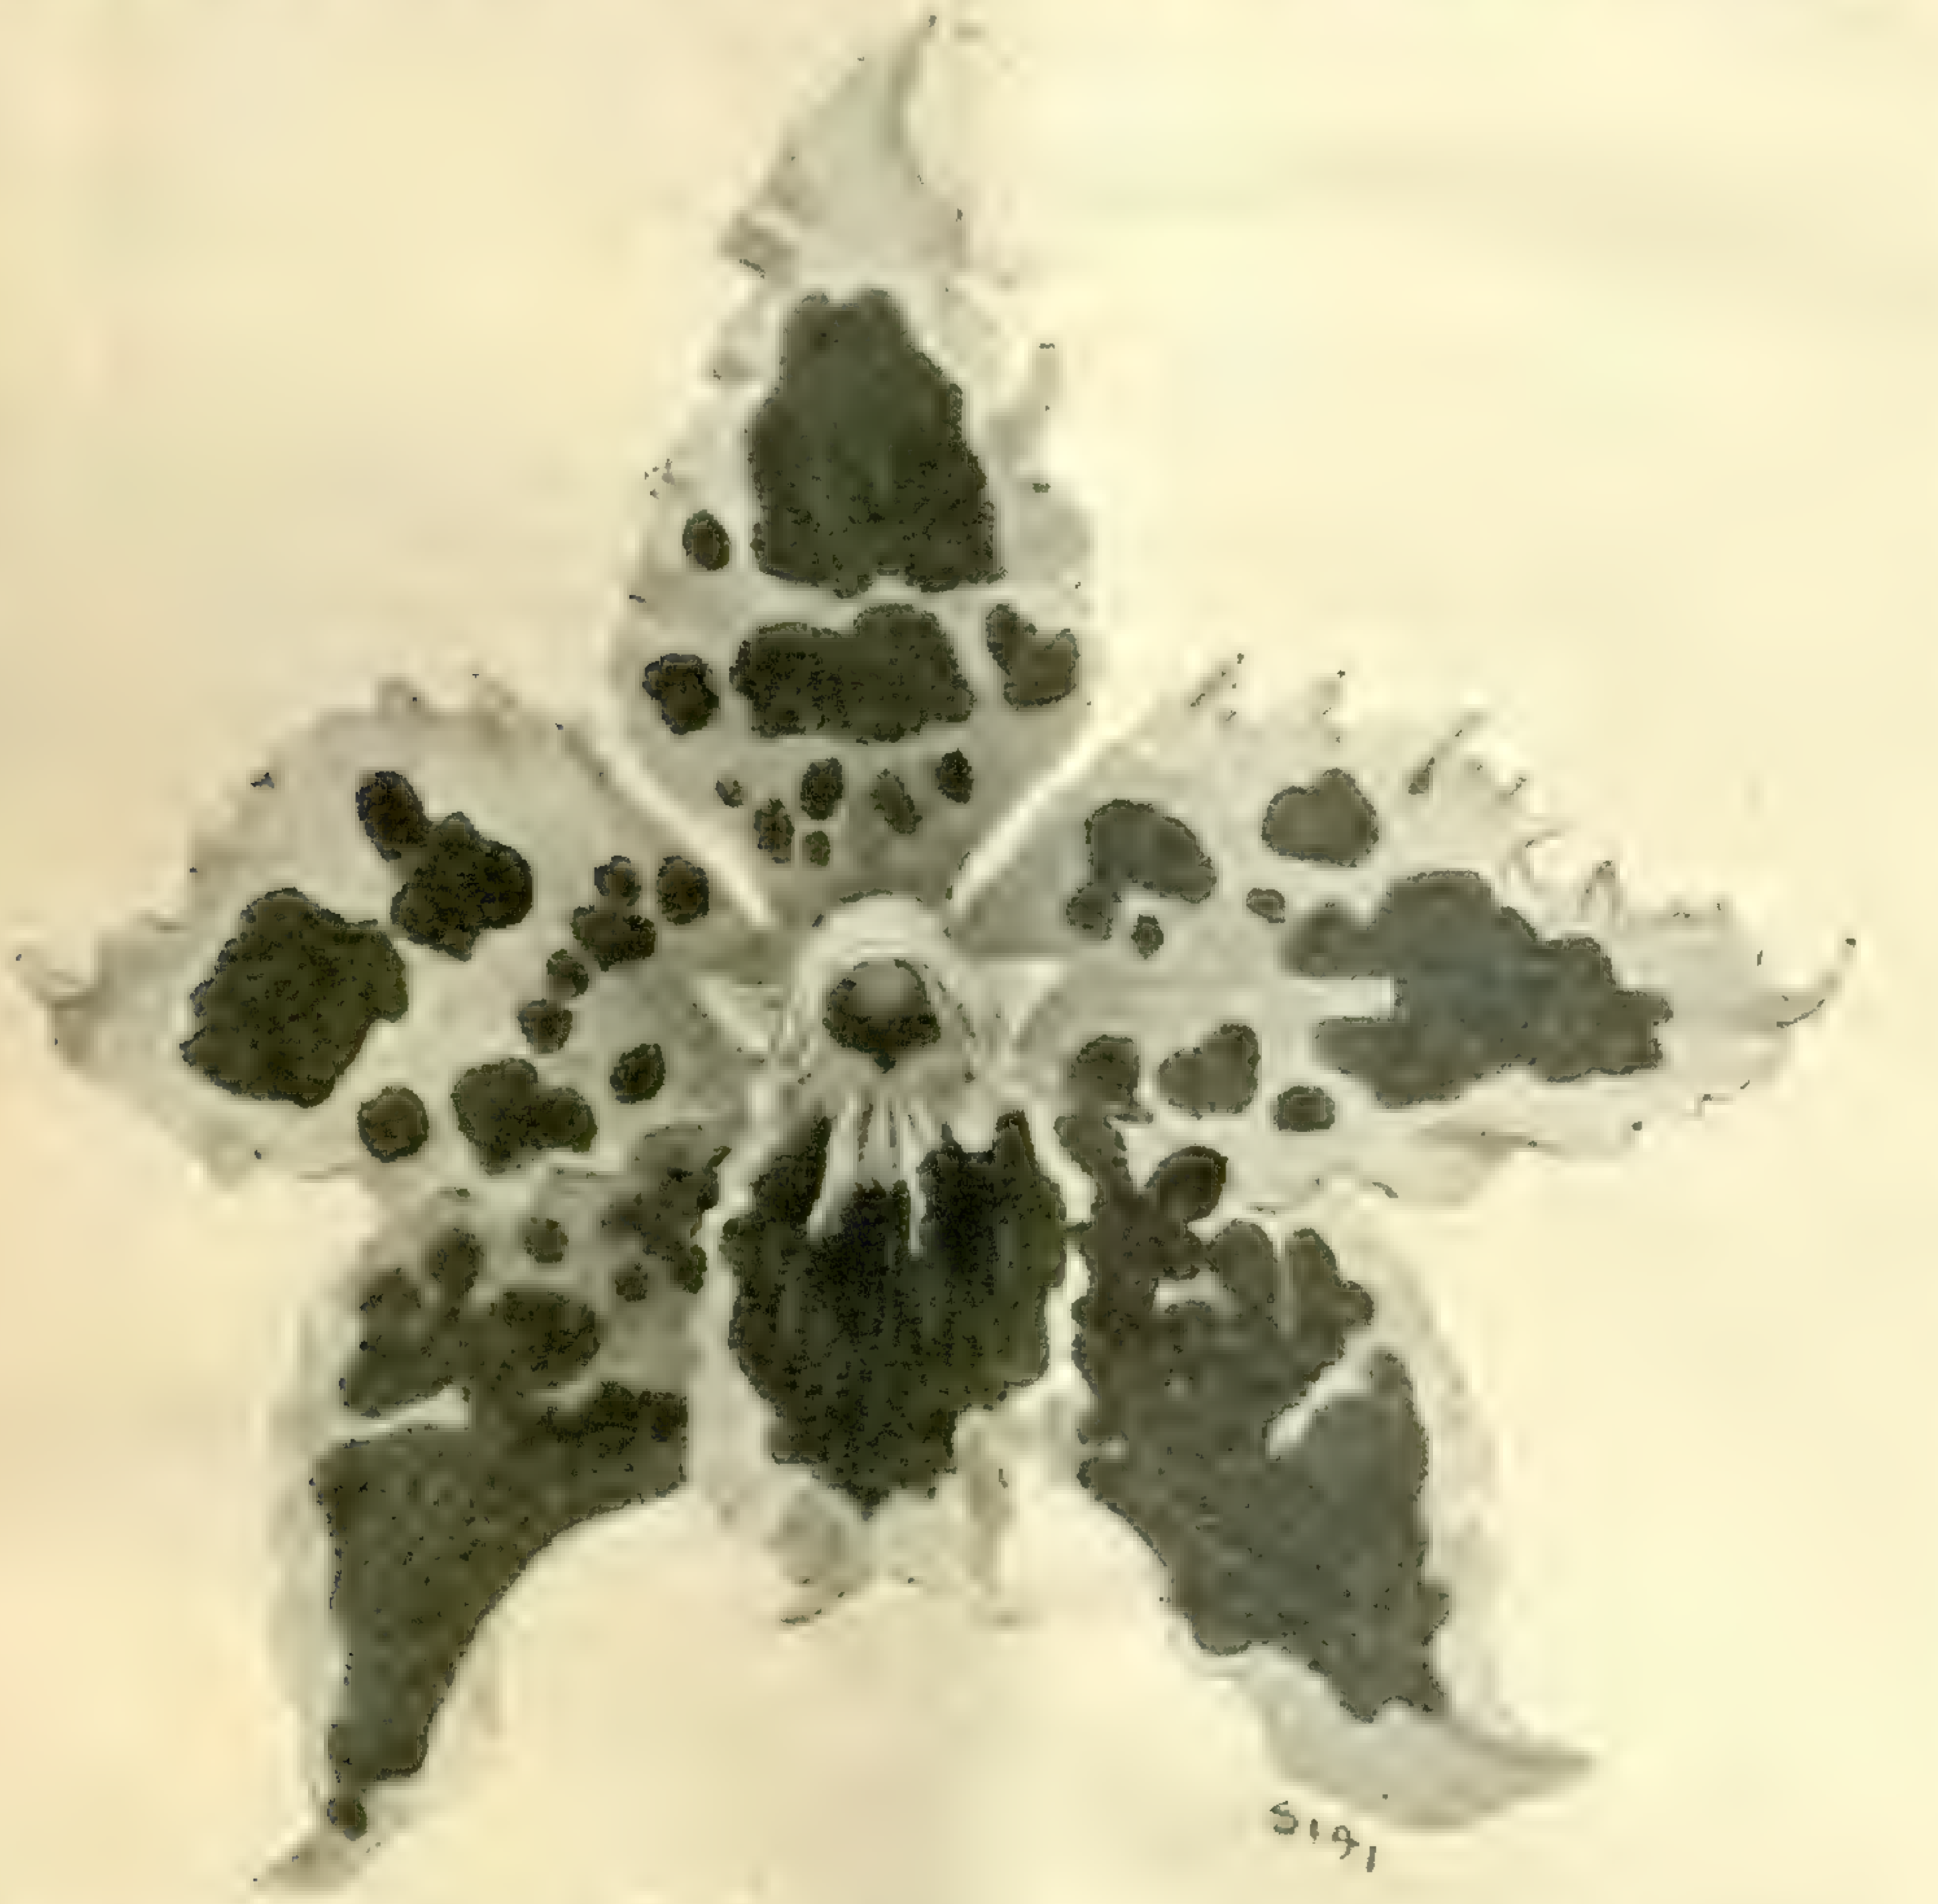
NOTES ON ORCHIDS.

DENDROBIUM RAINBOW.

THIS is undoubtedly one of the most beautiful dendrobium hybrids yet raised; it is the result of crossing D. Findlayana with D. Ainsworthi. Its flowers are of good substance, each measuring three and a half inches across, the sepals slightly twisted, broad and white; petals tipped with heliotrope; lip pure white, measurone and a quarter inches across, tipped with heliotrope, and the throat having a large blotch of deep claret colour, surrounded by a light orange zone. A fine plant of this handsome hybrid was recently in flower in the collection of H. H. Bolton. Esq., Height Side, Newchurch, Manchester, carrying about twenty flowers, and was exhibited by the gardener, Mr. W. Eastwood, at the Manchester and North of England Orchid Society meeting on February 10 of this year, when it was unanimously awarded a F.C C. It was raised in the celebrated collection of Sir Trevor Lawrence, Burford. G. S.

ODONTOGLOSSUM WILCKEANUM PITTIÆ.

This wondrously beautiful odontoglot is certainly the finest of its section. Not only does its exquisite chocolate markings on a yellow ground commend it to the fancier, but its robustness commends it to the orchid grower in general, and reflects considerable credit upon Mr. R. Aldous, gardener to its owner, H. T. Pitt, Esq., Rosslyn, Stamford Hill. Each bloom measures about three-and-a-half inches across, and has all the segments more or less fringed along the margin.



ODONTOGLOSSUM WILCKEANUM PITTIÆ. (Flowers yellow and chocolate.)

When exhibited before a recent meeting of the R H.S., this fine orchid, carrying seventeen or eighteen flowers on one spike, merited a first-class certificate. The nearest relation to O. Wilckeanum Pittiæ is probably O. W. Queen and Empress, a beautiful form in Baron Schröder's collection at The Dell, Egham.

EPIDENDRUM XANTHINUM.

One of the most showy of epidendrums is the Brazilian E. xanthinum, a species discovered by Von Martius, in the province of Minas Geraes. It is tufted in growth, and the long slender stems, clothed with two rows of linear-oblong leaves, terminate in the flowering season with a large-clustered head of rich, golden flowers, each flower about three quarters of an inch across; the lip is an attractive organ, its three lobes being exquisitely fringed. The species is generally amenable to cultivation, and may be grown in an intermediate house, or even in the cool house for the greater part of the year. When in flower it is a fine orchid for association with palms, &c., for grouping, as its long growths and effective racemes give additional grace and colour to the arrangement. This old orchid is figured in the *Bot. Mag.*, t. 7,586.

CYPRIPEDIUM BEECKMANI.

We have previously described this unique and handsome hybrid cypripedium on the occasion of its appearance before the R.H.S. in November last. It has Cypripedium Boxalli superbum as one parent and C. bellatulum is questionably recorded as the other. Whatever its parents it is a fine orchid, partaking largely of the form and size of the seed parent. The green, white margined dorsal sepal is broad and spotted with dark vinous purple; petals broadening towards the apex, rich reddish purple brown, margined with yellowish green; lip reddish purple brown tinged with rose and greenish yellow. This hybrid, named after Mons. Eugene Beeckman, chief of the private department at L'Horticulture Internationale, is admirably figured in *Lindenia* t. 600.

Large Ivy Stem.—Professor Henslow exhibited at the recent meeting of R.H.S. a section of ivy, some ten by eight inches in diameter. It grew round a tall holly, about fifty feet in height, at Zeals Rectory, Wilts.

GLADIOLI.

WITH the season of gladiolus planting now at hand, the thoughts of those who grow these remarkably beautiful flowers turn instinctively to those who have done so much to improve both the constitutional vigour of the plant and increase its floral productiveness and beauty. Among the names of those who, at home and abroad, have made such wonderful progress in the provision of new varieties for the embellishment of our gardens and the adornment of our houses, one comes forcibly to mind by reason of the rapidity with which it has become prominent in this connexion, and because of the extreme beauty of his productions. The reference is to Mr. J. Burrell, of Messrs. Burrell and Co., Cambridge. Mr. Burrell entered with vigour a few years ago into the business of raising gladiolus, chiefly of the gandavensis section. So skilfully has cross fertilisation and the raising of seedlings been performed, that a very high percentage of the forms raised are of the greatest horticultural value, as all who have seen the exhibits staged by the Cambridge firm will admit. Beauty in colour and form, stately and vigorous, well-furnished spikes, characterise all the Cambridge productions, while their comparative youthfulness and the first-rate methods of cultivation adopted ensure fine corms that invariably give a good account of themselves if well cared for.

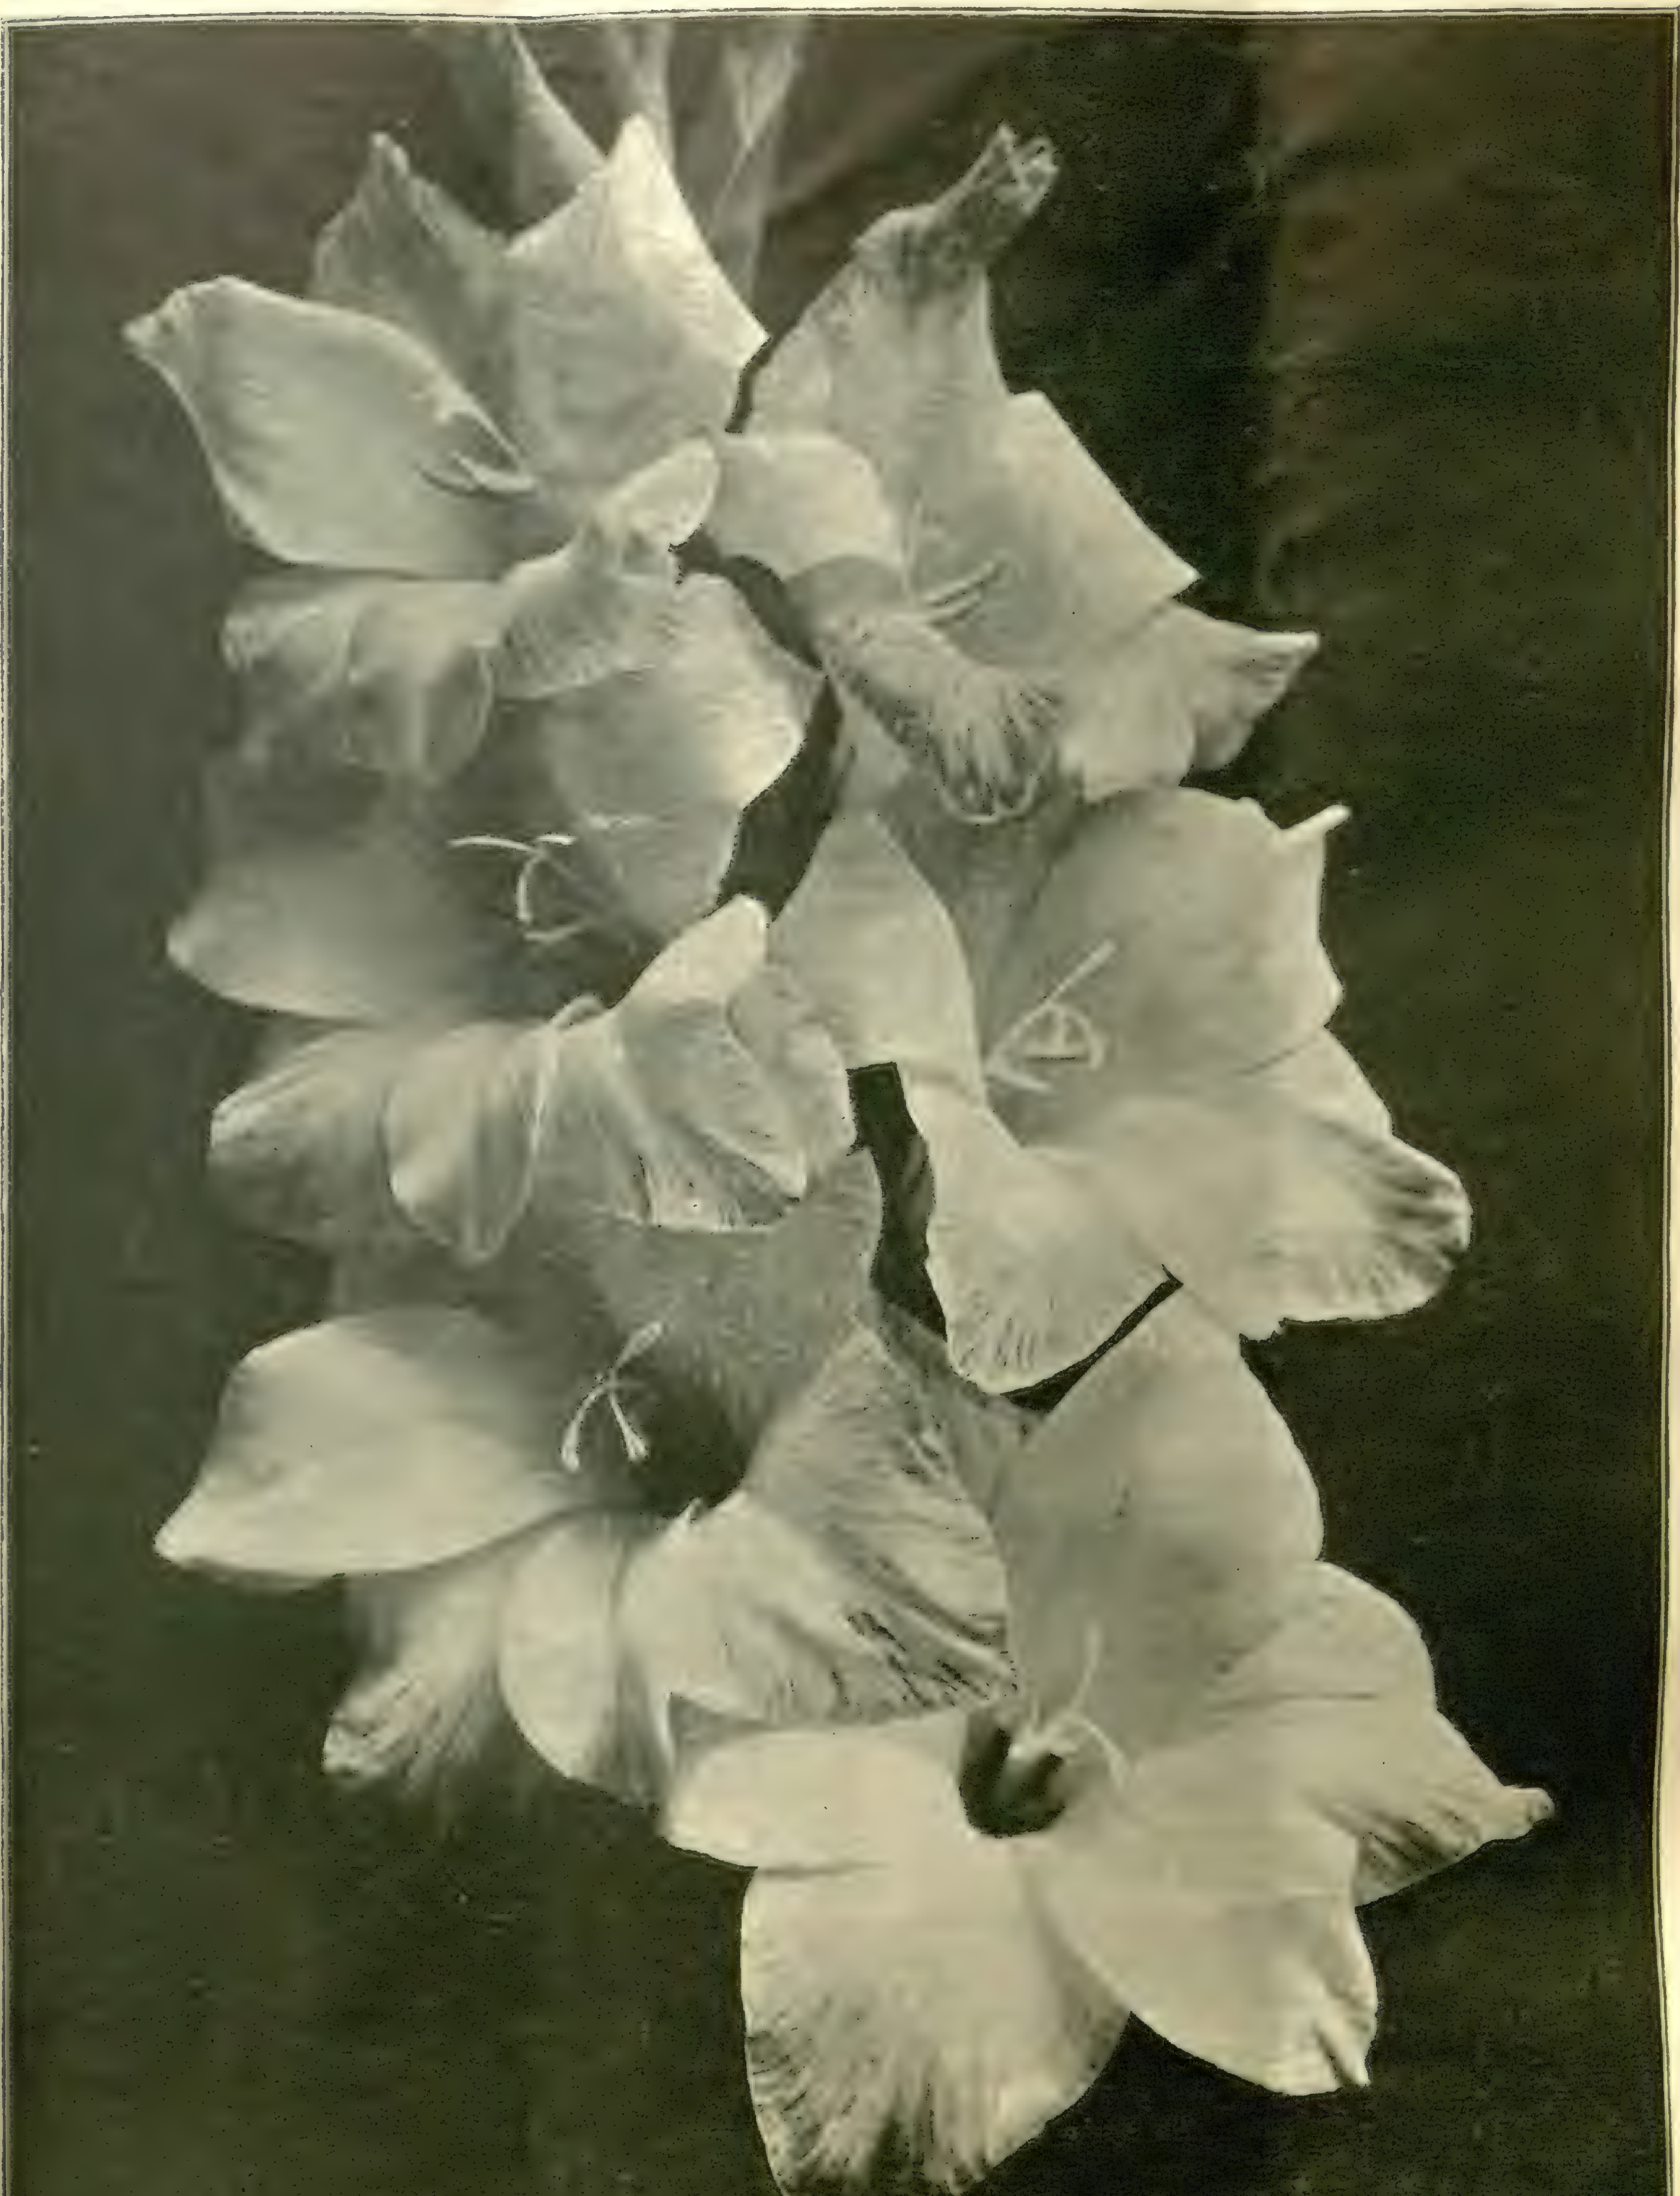
Opinions differ among amateur growers as to the kind of soil best suited to gladiolus culture, but Mr. Burrell, having grown gladioli in all kinds of soils and mixtures, has had opportunities for judging which are best, and his conclusion is, the best results are obtained on a somewhat heavy yellow loam of an adhesive nature, without any admixture of sand. On such a soil he is able year after year to keep up a vigorous and healthy stock of gladioli, and no matter whether the seasons be hot or cold, dry or wet, always has a good measure of success in producing flowers and corms. His conclusions have reference to the fine hybrids of the gandavensis section, but it may be taken for granted that whatever suits these, as regards soil and general conditions, will also suit the purpureo-auratus hybrids and Saundersi varieties, and these three sections contain all the most beautiful late-blooming gladioli worth cultivating for the beauty of their flowers. In recommending a somewhat heavy loam Mr. Burrell does not forget that splendid flowers of gladioli are produced in soils of a light, sandy, and even gravelly nature. In fact, as regards the mere production of fine flowers, this may be done in almost any kind of soil whatever; but a cultivator is only really successful when, in addition to fine flowers, he is also able to keep up a healthy stock year after year, and this is more likely to be attained in a good holding loam rather than in any other kind of soil, at all events so far as the drier and warmer counties of England are concerned. Where the rainfall is excessive and the climate less warm and sunny, some modification of the foregoing opinion might be necessary, and a soil of a lighter nature found more suitable. Although it does not appear that the gandavensis hybrids flourish on stiff clay, they succeed admirably near Cambridge on a soil closely approaching clay, but where the drainage is good and the rainfall light—an average of about eighteen inches a year.

Excessive manuring Mr. Burrell considers extremely harmful, and likely to generate a disease with which the whole genus is afflicted more or less, according to the nature of the cultivation given it. At Cambridge the corms are grown on ground which has been well manured for the previous crop, and this produces quite as good results as when the ground is specially manured for the gladioli alone. An excess of humus in the soil is distinctly harmful, and the stock will remain far healthier in what is termed clean soil. At various times the gladioli have received moderate dressings of bone meal, fish manure, muriate of potash, and other artificial manures, but all with doubtful results. Sometimes a slight mulching with fresh straw litter is given, but generally those grown without any mulching do equally well. Liquid manure in any form whatever Mr. Burrell never gives his gladioli.

For the fungus disease which attacks the corms of gladioli, and with which the whole genus appears to be more or less affected, no remedy for complete eradication has yet been found. Various suggestions have been thrown out, among others that of breeding new races direct from the species; and some importance has been attached to the reintroduction of G. oppositiflorus, a plant of considerable vigour. A gladiolus with its flowers placed in opposite directions on the spike is a poor garden plant compared to one with its flowers all facing in one direction, and Mr. Burrell has no faith in going back to the species as a remedy for improving constitution. He rather recommends clean cultivation, the selection of vigorous hybrids as parents, and the raising of young stock to replace worn-out corms, as is done in the case of most garden plants. His own annual loss from disease barely reaches ten per cent.

With reference to what the future may hold for gladiolus Mr. Burrell still holds the opinion expressed before one of the 1896 R.H.S. meetings, that we shall have at no distant date remarkable and new colours, including all shades of blue, and giving flowers and spikes equal in size to the fine gandavensis varieties, and, like the latter, opening a considerable number of flowers at the same time without loss of constitution. As many of the hybrids of gandavensis are as yet unrivalled in vigour, and beauty of flower and spikes, he does not fear loss of constitution by an infusion of the good qualities of these into other sections in order to obtain a greater variety of novel colours.

The remarkably handsome variety Lauretta, of which an illustration is given herewith, is one of the fine seedlings raised by Mr. Burrell. The illustration is reproduced direct from a photograph, and represents a short spike that we specially selected for the purpose of showing the flowers their natural size. These are of superb form and substance, and are white, shaded pink and flaked and striped with rose, and a more exquisite combination of colour it would be difficult to conceive. Other of the Cambridge-raised gladioli of recent introduction and special excellence comprise Bernice, pale yellow; Comedy, soft salmon-pink with white centre and richly painted with crimson; Cygnet, delicate lemon



GLADIOLUS LAURETTA. (Flowers white, pink, and rose.)

tinted white, very chaste and beautiful; Dora Craven, white, with carmine blotch on the segments: Ella, lilac, shaded rose, with crimson blotch on the segments; Elvira, white, suffused rose and flaked with red; Fiametta, rich salmon rose, very distinct and beautiful; Gertrude, white suffused with rose and marked with a few crimson stripes; Grand Mogul, cerise, heavily painted with mulberry and tinted with slate colour at the margin; Hilda, ivory white flaked with rose at the margin; Martial, rich crimson, flaked with scarlet and dark crimson, effective; and Rosalie, delicate salmon pink.

PROPORTIONING PRIZES TO POINTS.

SHOULD it happen that any readers of the GARDENERS' MAGAZINE have been interested in the note by A. D. on the new departure at Shrewsbury in proportioning the prizes to the points gained in two large classes, there may be further interest in the knowledge that the system is already in force on a very extensive scale in the county of Kent. Acting on a suggestion by the Lord Lieutenant (Earl Stanhope), the Technical Education Committee of the Kent County Council established a series of garden, allotment, and show competitions three years ago, giving a set of prizes, value 50s., to each village where lectures on practical horticulture were delivered. The money was divided into four prizes of the respective values of £1, 15s., 10s., and 5s., which for cottagers are, it will be agreed, not illiberal. Certainly they are above the average. Upwards of fifty village competitions resulted. In the course of my judicial work, I was struck by the number of instances in which a few points separated all the prize-winners. In some cases only four or five marks represented the difference between the first and fourth gardens, yet the difference in the prizes was 15s. Another fact that arrested my attention was that in some villages, where the cultural level was low, a competitor secured £1 with less marks than were earned by a second competitor in another village, yet who, owing to the higher level of the work there, only secured a fourth prize. Both these things seemed to me to call for rectification, and after due reflection I submitted to the committee a scheme for establishing an entirely new basis of awards. This was to give prizes at the rate of one penny per point, and do away with fixed prizes altogether. The scheme has worked well. To give an example I open my judging book at random and take the following instance: (1) A, 173 points, prize 14s. 5d.; (2) B, 168 points, 14s.; (3) C, 163 points, 13s. 7d.; (4) D, 152 points, 12s. 8d.; total, £2 14s. 8d. It will thus be seen that the prizes are in exact proportion to the merits of the gardens, as they could not be on a fixed basis.

On this system it is advisable not to fix the number of prizes. We do not do so in Kent. We have a minimum standard, and if it is not reached no prize is awarded, even if the rule means excluding every competitor, but things have never been so bad as that. On the other hand, we have a maximum standard, every competitor attaining which gets a prize to the full value of his points. This insures that good centres get more money than weak ones, as they deserve to do. Allowance is made for any striking disadvantage of soil. We have centres getting five, six, and even seven prizes, and earning from fifty to seventy-five per cent. more than they did on the old system. The extra money comes in the main from the weak centres, as the total cost to the committee is about the same as it was before. But (and this is instructive) there are cases where a low-point centre under the fixed prize system has become a high-point centre under the proportionate system, the competitors having perceived the necessity of pulling themselves together.

The more this system is studied the more plainly its justice and workability become manifest. Many authorities have expressed their approval of it. Mr. George Gordon was one of the first, if I remember aright, to instantaneously perceive its advantages, and Mr. John Wright, with his great judicial experience, approves its simplicity and efficacy. It may be asked how the system is applied to collections of produce. It is as follows: A standard is fixed for each vegetable, of which we usually ask for nine kinds. The average marks are, say, eight; thus it is possible for a competitor to get seventy-two altogether. This is a much smaller number than can be earned with a plot, so we raise the "scale of pay" to 2d. per point—result, a first prize of 12s. No. 2 may have 66 marks, prize 11s.; No. 3, 60 marks, prize 10s.; No. 4, 54 marks, prize 9s.; and No. 5, 50 marks, prize 8s. 4d.; total, £2 10s. 4d. If others reached a standard of two-thirds the maximum, *i.e.*, 48 marks, more prizes would be given. A rich society giving about £25 to one important class could follow the same system, but calculating the prizes at 1s. or 2s. per point instead of a penny or twopence. To my mind the fixed number of prizes is the weak point in the Shrewsbury arrangement. The number of prizes, like the value, ought to be decided by one thing—merit alone.

Although I have had many inquiries about the Kent system, I have not hitherto drawn prominent attention to it in any of the leading organs of horticultural opinion. I do so now partly because the subject is exciting attention, partly because honour for the innovation belongs, not to Shrewsbury, but to the Kent Technical Education Committee—a body which is unceasing in its endeavours to give practical help to all classes of horticulturists.

W. P. WRIGHT, *Horticultural Superintendent,*
Kent C.C. Technical Education Committee.

ROSE SHOW FIXTURES FOR 1898.

June 15 (Wednesday).—York.*
,, 16 (Thursday).—Colchester.
,, 23 (Thursday).—Bath (N.R.S.).
,, 25 (Saturday).—Windsor.
,, 28 (Tuesday).—Southampton,† Sutton, and Westminster (R.H.S.).
,, 29 (Wednesday).—Canterbury, Croydon, and Richmond, Surrey.
,, 30 (Thursday).—Eltham, Gloucester, and Norwich.
July 2 (Saturday).—Crystal Palace (N.R.S.).
,, 5 (Tuesday).—Harrow, Redhill
,, 6 (Wednesday).—Farningham, Hanley, Reigate.
,, 8 (Friday).—Ulverston.
,, 12 (Tuesday).—Wolverhampton.*
,, 13 (Wednesday).—Newcastle-on-Tyne.*
,, 14 (Thursday).—Halifax (N.R.S.), Canterbury (Hospital Fund), and Helensburgh.
,, 26 (Tuesday).—Tibshelf.

* Shows lasting three days. † Shows lasting two days.

The next list of fixtures will appear early in April. In the meantime I shall be glad to receive the dates of any rose shows (or other horticultural exhibitions where roses form a leading feature) for insertion in that list.

Rosebank, Berkhamsted, Herts. EDWARD MAWLEY.

FIDLER AND SONS, READING.

THE ancient and interesting town of Reading numbers among its inhabitants not a few men remarkable alike for their business ability and enterprise, and the [illegible] they have risen from comparative obscurity to be among the leaders of their profession as well as capable and generous townsmen. One example especially appeals to us as horticulturists, and we feel sure that our readers will be interested in a brief account of the firm of Messrs. Fidler and Sons, Reading, a firm [illegible] throughout the world, or, at least, wherever potatos of high quality are grown.

On a very small scale the business that has now reached such considerable dimensions was commenced by the father of the present proprietor some forty years ago. The great up-building of the concern was left, however, for Mr. J. C. Fidler, who now controls it, and it is a monument to his industry and ability. Enterprise, combined with clear foresight, has characterised all his undertakings, and his aim as a business man has always been to sell the best possible article, and to sell it as cheaply as possible. Mr. J. C. Fidler is sole proprietor of the business, but is assisted in its conduct by his two sons. Some idea of the extent of the seed and potato trade carried on in the new premises the firm occupies in Friar Street, will be gathered from the fact that not less than a hundred persons are herein employed. The block of buildings comprising warehouses, order-rooms, offices, and shop, have been built by Mr. Fidler to suit the requirements of the business, and they are lighted throughout by electricity. At present the output of garden seeds is slackening, but the almost empty bins and shelves show that there has been a remarkable run on the leading kinds of vegetable seeds supplied by the firm. One shelf was pointed out to us where at the beginning of the season over five tons of a certain culinary pea were packed in pint and quart packets; this is now almost empty. Very many of the bins in the big order-room have to be filled over and over again from the warehouses above to meet the demand that has been exceptionally heavy this year. Farm seeds are largely supplied by Messrs. Fidler and Sons, and the huge stocks of mangold, turnip, swede, cabbage, clovers, beans, &c., so largely used in farming, represent a very large sum of money; orders for these are now coming in apace, and the building seems pervaded with a sense of unostentatious prosperity.

MR. J. C. FIDLER.

Potatos.

If there is one branch of the business of seedsmen in which the Messrs. Fidler excel, it is in the production and introduction of potatos. To raise seedling potatos does not require much space, but to properly test them when raised and compare them with tried varieties of high quality means the cultivation of a large area. To ensure satisfactory trials Mr. Fidler farms some five hundred acres at Southcote, Battle Farm, and Honey End, all within easy distance of Reading, and here all the new or promising potatos are thoroughly tested ere they are distributed. With an experience extending over forty years, Mr. J. C. Fidler understands as much about potatos as any man living, so that his views are worth recording. In the production of a new potato three things must be aimed at, viz., strong parentage, fine quality, and high cropping power. An ideal potato is one that is kidney-shaped, a heavy cropper, strong constitutionally, and [illegible] tubers that are handsome in appearance, floury when cooked, and finely flavoured. The nearer a potato is to such an ideal the more popular it becomes, though, as Mr. Fidler states, there are a few people who like what is generally known as a "waxy" potato, and on the Continent these hard potatos find considerable favour for "chips" and stews. The variety that has done more than others to give fine constitution and high cropping powers to its progeny is Champion. Consequently this variety, either as parent or grand-parent, has exercised considerable [illegible] in the potatos sent out by the Messrs. Fidler. The shape of a potato has [illegible] to do with its popularity, for while excellent quality is found in round and [illegible] shaped sorts, yet the great wholesale demand is for kidneys, and this [illegible] because such are the more easily peeled, and the largest buyers are hotel [illegible] and restaurateurs. With regard to constitution Mr. Fidler finds no [illegible] between, rounds, pebble-shaped, or kidney varieties, and he should know, [illegible] sidering the amount he grows on his own farm and in other parts of the country. The output of the firm, for potatos, from the beginning of November to April, including both eating and seed tubers, averages over three hundred tons per week. The highest output in one week was six hundred and twenty tons.

The average life of a potato, according to Mr. Fidler, is twelve years; [illegible] that age a variety loses vigour, no matter how well grown or how carefully [illegible] is changed. Unfortunately for the great body of potato growers and [illegible] new potato is looked at with some degree of diffidence for the first four or five years of its public life, and as a result it has run half its course ere it becomes properly appreciated and widely grown. Naturally, those who make a speciality of raising new potatos, cannot, by reason of the expense incurred, sell sets of a new seedling as cheaply as those of a variety already a proved commercial success, so that the raiser is not all to blame, as some think. To succesfully combat the potato disease there must be a succession of new and vigorous potatos, and, to bring these before the public as their merits deserve, Mr. Fidler looks hopefully to agricultural and horticultural societies and to technical education centres, where trial grounds are managed. Potatos ranking next to wheat among the chief foods of the country, the discovery of meritorious potatos by means of strictly independent trials in various parts of the country seems a necessity. For such independent trials all new potatos should be sent immediately introduced, so that with those varieties proving satisfactory in every respect growers may, after viewing the crop or reading the reports, be emboldened to plant it largely, and so have the benefit of heavier crops than would result from a variety that had lost the vigour of youth. Probably no disease-proof potato will ever be raised, but the disease is most successfully resisted by new and strong-growing varieties. The expense attaching to potato raising may be guessed at by Mr. Fidler's observation that only from five to ten per cent. of the new potatos that are finally put on trial after raising ever become a commercial success. This means that the set of Fidler's potatos listed in the 1898 catalogue is the *crême de la crême* of from two to four hundred seedlings put on trial.

Mr. Fidler grows all the leading varieties of potatos by whomsoever raised, and he finds that by careful cultivation and spraying he has almost an immunity from disease. In ordinary seasons spraying is done twice by means of a Strawson machine, and the liquid used is Strawsonite. This fungicide Mr. Fidler speaks highly of, as he considers it not only effectual if properly applied (spraying twice in wet seasons), but has found that plots sprayed with it show a heavier yield of tubers than those unsprayed.

Fidlers' Potatos.

During the long period that the Messrs. Fidler have been raising new potatos, they have placed upon the market a considerable number of varieties. Some have had their day, and been superseded by those now so well known. Others have scarcely yet been tried since introduction, but they have a good future before them. Among the most important and successful maincrop varieties introduced have been Fidlers' Reading Giant, and Fidlers' Colossal, both of which are now quoted on all the leading potato markets, and cultivated wherever potatos are grown in quantity. Improved Imperator, another of the firm's introduction, differs from the type in having shallower eyes and more refined appearance and quality; two other white, round potatos that have been eminently successful are Fidlers' Prizewinner and Cluster Regent. Among other introductions are Challenger, Onward, Early May, Rising Star, Hercules, White Rose, Prolific, Success, Improved International, Monarch, and Improved Ashleaf, all varieties of proved excellence and heavy cropping powers.

The two newest potatos raised by this firm are Fidlers' Early Eclipse and Fidlers' Queen. The former was introduced in 1897; it is a white kidney that matures early, and is of first-rate quality. Already it is being grown extensively in Yorkshire as a market variety Fidlers' Queen is an exceptionally fine white kidney potato that the Messrs. Fidler are distributing for the first time this year. It is the result of a cross between Fidlers' Reading Giant and Sutton's Early Regent, and has produced three tons per acre more than the Reading Giant, besides being ready to lift quite fourteen days earlier. The tubers are of full medium size, flattish, with white, rough skin, and white flesh of excellent flavour. In habit it is strong and robust, resisting disease in a remarkable degree. Having studied all aspects of the potato trade, Mr. J. C. Fidler has not overlooked the Jersey crops, and he is confident that in Fidlers' Queen the Channel Islanders will have a potato suitable for their early cultivation, and one that will prevent the losses, so frequent of late years, resulting from the deterioration of the varieties so long in use in Jersey and Guernsey. Mr. Fidler is offering gold, silver, and bronze medals, in addition to cash prizes, for the best crops of Fidlers' Queen raised in Jersey from 1 lb. weight of sets. By this means he hopes to popularise the variety before it loses vigour.

Mr. J. C. Fidler.

The head of the firm is in many respects a remarkable man. He is the essence of geniality and has a physique that would in years past have recommended him to the recruiting sergeants of the Life or Horse Guards. His enterprise is seen not only in his farms and in the big potato and seed business he has built up but also in his contributions to the improvement of the town of Reading. Whole blocks of old fashioned shops and houses have been acquired by him, and in their places he has erected handsome shops and offices, arcades, and public institutions, which are a source of profit to himself and attraction to the townspeople. It would seem that Mr. Fidler values modern methods of procedure; he saw a great future for electric light, and backed his opinion to such a tune that he is now director of the Reading Electric Lighting Company. His wholesale and retail fruit business, added to choice vegetables, forms one of the smaller items, but many would wonder where Mr. Fiddler finds an outlet for the quantities of cases of oranges, lemons, bananas, &c., that he imports, and which in varying numbers are always to be seen near the Friar Street offices. Mr. Fidler loves to do things on a large scale, as becomes a large man with a large heart. Many schemes he has under consideration, and some of these were unfolded to the writer a few days ago; as, however, they might startle folks unduly they must be treated *sub rosa.* One scheme that has proved an unqualified success Mr. Fidler did not unfold, but it is a fact nevertheless, that amid all the complications of a big concern, or combination of concerns, he has time to be generous. It is to his credit that on the occasion of the Jubilee celebrations last year Mr. Fidler provided, entirely at his own cost tea for fifteen thousand (15,000) children at Reading, and, in addition, gave tea to about a thousand friends and helpers who had previously assisted the children to enjoy themselves. Mr. Fidler has both deserved and commanded success as a townsman and as a horticulturist, and in the latter connection the records of the Royal Horticultural Society bear ample testimony to the excellence of his introductions.

The Green Fruit Buyers' Association was formed a few days ago for the express object of securing needful reform in the methods of purchasing fruits from brokers that now obtain. The chief complaint is against the system of purchasing oranges, and the association will strongly advocate an extension of the Liverpool method which permits inspection of the boxes at the time of buying, against the present haphazard system of marking the boxes before examining their contents, which does not permit the buyer to estimate the percentage of bad fruits per box. The association was instituted at a meeting held in the Sale Rooms, Pudding Lane, under the presidency of Mr. Hoar.

WORK FOR THE WEEK.

WARM ORCHIDS.

THE sun has now considerable power, consequently shading will have to be considered. The glass on all warm orchid houses ought to be well examined, and all squares of inferior quality removed and replaced with good clear glass. I have many times noticed large yellow patches in the centre of a leaf, and on further examination a bubble or flaw in the glass above will be found, and this very often is the cause of injury. The houses generally, during the weather we are having, vary very much in temperature. This rises high by day and falls quickly towards evening. My advice at such times is not to give much top veutilation, for when the damping is done in the afternoon, and all ventilators closed, much moisture settles on the plants, and the contrast in atmospheric conditions is too great. If the blinds are lowered during the hottest part of the day, and the ventilators used carefully, a free circulation of air will be kept up and humidity retained. Potting, top-dressing, &c., &c., will require every care and all possible attention at the present season. Thunia Marshalli and T. Bensoniæ are rejected by many orchid growers, perhaps because of the short duration of the individual flowers; these orchids are, nevertheless, well worthy of cultivation owing to their extreme beauty. They are now pushing forth their young growths, and must be repotted at once; being strong-rooted subjects they require plenty of pot room and a mixture of rough peat and loam in equal parts, and a little leaf mould, a little silver sand, and chopped sphagnum added. A neat stick must be tied to each growth, and sufficient space allowed between them for their development. The pots must be well drained, and the plants kept below the rim to allow for plenty of water during active growth.

Calanthes of the deciduous sections are not highly valued amongst connoisseurs, but what orchids are more graceful and useful? At the present time, if they have been rested in the ordinary way calanthes will have to be repotted, and the sooner this is done the better, for the roots grow quickly, and are easily broken. Calanthes do well in either pots or baskets suspended from the roof, in a shady position in any warm moist structure; a melon house is a very suitable place, but under any conditions the syringe must not be used on the foliage, or disease is very apt to appear; a good compost for these calanthes is fibrous loam, and about a fourth part of peat, rough leaf mould, and a little dried cow manure, with some silver sand; the pots should be drained to about a third of their depth, and watering must be done very cautiously until growth is vigorous. Cattleya Lawrenceana is fast pushing up its sheaths, and must be placed at the warm end of the cattleya house, and in a dry position; this species appears to absorb moisture more readily than most cattleyas. C. Mendeli and C. Mossiæ are more or less sheathed, and will require more water. Such as are failing to show indications of flowering may be repotted if required, and those with sheaths and making new roots may be top-dressed, providing great care be taken not to disturb the position of the plant in the pot. Dendrobiums generally will now be at their best, and providing a good display. This will afford those interested in hybridising a good opportunity for selecting parents, and this ought to be a very important consideration. We have discarded many weedy dendrobiums from our collections, forms that would not have been produced had the hybridiser used a little judgment in the selection of parent.—F. STAFFORD, *Tyntesfield Gardens.*

CONSERVATORY AND GREENHOUSE.

THE potting on of chrysanthemums, and providing suitable positions for the young plants, will entail both time and forethought for some weeks to come, as most cool houses and frames will be well stocked with bedding and other subjects; and to obtain the best results next autumn, the plants must not be starved in small pots at this season, nor crowded together. For the most part, the desired number will be now well rooted in sixties, and most probably occupying shelves near the glass in late fruit houses and the like. This is a grand place for them up to a certain stage, as it ensures sturdy growth. As the sun gains power, the small amount of soil quickly dries, so that much attention will be needed to keep them moist. It would prove a saving of labour, as the plants are placed into thirty-twos, to arrange them on a bed of ashes in a shallow frame and a great advantage to the plants also. In such a position they can be kept rather close for the first few days after potting to give them a start, and so long as frost is excluded, there is no fear of the low temperature checking their progress, as they simply revel under these conditions, while they quickly become puny when confined in a close, humid atmosphere. It is very necessary at each future potting to use a compost both coarser in character and containing more feeding properties than is possible or desirable during the early stages. Turfy loam pulled to pieces, with a little leafmould, road grit, and a sprinkling of bone meal, will answer the requirements of the roots until the final potting. It must be remembered that in the ordinary course the plants will remain in thirty-twos for many weeks, therefore the more soil that can be placed in the pot without ramming it too hard the better it will be for them, and the valuable space should not be sacrificed by placing a lot of crocks in the bottom, one broad one being all that is necessary with proper compost and careful watering. Plants that have been growing in peach houses are not always free of green fly, and it is necessary to examine them, especially at the tips, and cleanse them where necessary before they are potted and so save much trouble later on. The frame should be in an open position, though sheltered from cutting winds, and no attempt should be made to shade the plants, a mere dimming overhead if the foliage appears limp after potting is all that is required.

The present time should not be lost to strike a good batch of suitable varieties of zonal pelargoniums for winter flowering. These are indispensable in affording a brilliant display during the dullest months. It is best to place one cutting in each thumb pot, as such can be potted on when rooted without giving a check. Use sandy soil, and they strike freely in a warm greenhouse or frame. Pot up cannas that have been at rest during the winter, and as the plants are most suitable for decorating when grown in thirty-twos, many of the stools will require dividing. Until growth is well up the pots may stand close together in a warm place where they can be syringed overhead, but plenty of room and light must be afforded as they unfold their leaves. In most gardens every place will now be crowded, but the houses should be relieved as much as possible by the removal of many of the hardier plants to cold frames. Pot on autumn-sown intermediate stocks, and directly the flower buds are visible assist the roots with liquid manure once or twice a week. These will prove useful for cutting or furnishing window-boxes and the like later on. Among other seed that is being sown now, the Marguerite type of carnations should not be forgotten; rightly managed, they yield a wealth of sweet-scented flowers of all shades most of the winter. Sow in gentle heat, but harden the seedlings off as soon as possible after they are a couple of inches high, to cause them to make stocky growth. Keep them potted on as the roots require more room, and arrange them near the glass, pinching out the points of the longest shoots if the plants appear to be drawing up weakly. Late batches of cinerarias should be placed in a north house or pit, which will not only retard their flowering, proving an advantage at times, but the foliage and flowers come a much richer colour than when exposed to the sun. Sow successional batches of seed according to the demand there is for these plants, keep the soil thoroughly moist at all times, and stand the vessel containing the seed on a shelf in the stove, or, what is better, plunge it in a gentle hotbed. Prick off young stock, and keep them in a growing atmosphere for a few weeks onger before removing them to cooler quarters. The same remarks apply to primulas. Some do not trouble to save cyclamens after the first year, and trust to seedlings each season to furnish the plants. It is not desirable save any that are not of good form and colour, but with a good strain I prefer to grow the bulbs on for a year or two. In this case remove the plants as they pass out of flower to a cold pit, but water should be afforded regularly for a time, or the bulbs shrink and are much weakened. As the season is upon us when there will be a great demand for flowering plants and cut bloom, it is necessary to examine carefully the stock at command, hastening some and retarding others, so as to save disappointment.—RICHARD PARKER, *Goodwood Gardens.*

THE FLOWER GARDEN.

IN the frames placed on slight hot-beds, as recently advised, the annuals should now, or within the next week or two, be sown. Among the principal or most useful subjects best sown under glass are: zinnias, double and single; stocks, asters, salpiglossis, Nemesia strumosa, Phlox Drummondi, Gaillardia picta Lorenziana, and petunias. For sowing draw out shallow drills about four inches apart, covering the seeds at a depth according to their size. Very small seeds, as those of salpiglossis and petunias must be covered very slightly with finely-sifted soil. The frames should be kept close and shaded until the seedlings appear, afterwards gradually withholding the shading and admitting air in greater quantities as the seedlings develop, to prevent them drawing up spindly. Double zinnias, gaillardias, Phlox Drummondi, and marigolds in variety, form useful bedding plants, and may be used as substitutes for bedding pelargoniums. If the flower beds or borders are unoccupied in which these are to be planted, they may be lifted carefully from the frame early in May and be planted direct, affording shade with a few branches for a day or two if the weather be warm with bright sunshine. Stocks and asters may be treated in the same way, or be pricked off into other frames or a sheltered border as soon as large enough to handle. Seeds of Lobelia speciosa, pentstemons, and antirrhinums, if not already sown, should be put in forthwith, sowing in pans or boxes of light soil, and afterwards standing in a forcing house or on a good hot-bed. The same remark may apply to seeds of various subtropical bedding plants as ricinus, Cannabis gigantea, Melianthus major, nicotiana, Solanum robustum, variegated maize, and Perilla nankinensis. Dahlia roots stored in dark places under benches and similar positions and which it is intended to plant again in the borders, should be brought into a lighter position as soon as growth starts, or they may be placed together in a sheltered corner outside, and be just covered with leaf-soil or cocoanut fibre refuse. Treated thus the shoots made are strong and sturdy. A few mats or other covering should be kept in readiness, after growth has started, in the event of frost occurring. Young plants struck rom cuttings recently should be potted off singly and grown on for a short time in warmth. Cuttings may still be inserted if it is desired to further increase the choicer varieties. Tuberous begonias intended for bedding should be placed in pots of a suitable size, or they may be boxed up in leaf-soil or Jadoo fibre and be grown on sturdily to the end of May, using very little artificial heat. Seedlings should be forwarded for a time in a warm house. The potting off of bedding pelargoniums should now be completed, and the plants kept rather warmer until re-established. The propagation of irisines, coleus, alternantheras, Mesembryanthum cordifolium variegatum, ageratums, and similar subjects, may be carried on as fast as cuttings are obtainable; but several of these may be increased very rapidly a little later where frames or hot-beds are available for dibbling in the cuttings thickly, and where they strike in a few days and produce a further supply of cuttings to be treated in a similar manner.

The present and the next few weeks will be found a suitable time or the spring planting of rhododendrons and other American plants. Too late planting is not advisable, but with showery weather and an ample supply of water for application to the roots if required, these subjects may be moved with safety as late as the middle of May. At the time of writing the weather remains dry and cold, but this can scarcely last long, seeing the exceptionally dry winter and spring up to the present experienced, and the chances are that the coming month may be somewhat wet. Unless a heavy rainfall occur shortly, trees and shrubs generally must suffer considerably should a dry summer follow, the water supply in many districts being now extremely low. Where the natural soil consists of a heavy clay or much chalk it is useless planting rhododendrons, and in this case made-up beds or borders of a suitable compost becomes a necessity. This need not necessarily be of peat, as both rhododendrons and Ghent azaleas will grow and flower freely in a compost of sandy loam and leaf-soil, and as these subjects are chiefly surface rooting, a great depth of soil is not required. The plants should be pressed firmly in the soil, and given one good watering if the weather remains dry, afterwards applying a good mulch of rotten leaves or other suitable material. Kalmias, vacciniums, hollies, and other evergreen shrubs may also be safely planted. The appearance throughout the summer of ivy on walls and fences is much improved if all the old foliage be cut clean away at this season, a bright fresh growth soon taking the place of the old. This is easily done with hedge shears or reaping hook, afterwards giving a brush over with a birch broom to remove dirt and rubbish. Any necessary pruning of trees and shrubs should be finished off forthwith. Laurel hedges require a considerable amount of cutting to keep them in good form, and all small shoots are best cut with a knife or secateurs, while those of holly and box may be clipped with the hedge shears. Where mowing has not commenced, lawns should be swept and well rolled, and grass verges to walks and beds be neatly cut with the edging-iron, squeezing the turf down firmly first with a fairly heavy roller.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUITS.

THE season being an early one grafting should now be proceeded with, as there is no gain by delay, indeed, the reverse, if the trees and scions were prepared as previously advised. Grafting old trees, or those of any age, is so well understood that it is not necessary to detail the procedure here. I would, however, state that if a larger number of branches than is usual are left, I mean those of a smaller size, then by inserting more grafts the tree reaches a fruiting condition much sooner. There are various methods of grafting, but so far as I have seen, none are superior to whip grafting and crown grafting, of which there is an improved method, but not applicable in all cases; it is advised when the stock is large or old, or for trees that have been headed back. In whip grafting the scions should be selected with care, as it is necessary that they fit the stock as nearly as possible, and make a complete union. I prefer wax to clay for binding, as, if used n a warm state, it is superior in every way. Crown grafting is different, [illegible] the branches were previously shortened, the cut portion may now need [illegible] piecee removed to provide a new surface to work upon. There is no [illegible] scions freely on all branches able to support them, as it builds up the tree [illegible] sooner. Many condemn grafting, and would have all trees on their own [illegible] but by judicious grafting, and careful selection of stocks, we have largely [illegible] our best orchards and fruit gardens in the country. Pears should be taken [illegible] before apples, as they are more forward, and though slightly checked by [illegible] rosts, growth is more advanced than usual. Cherries should follow [illegible] much depends upon the state of the trees, and it may have been necessary [illegible] these trees ere this. Plums are often budded in summer; in fact, many [illegible] to adopt this plan with stone fruits, but if grafted there must be no longer [illegible] and apples may be done last, as these are the latest.

Now is the time to shorten back newly planted fruit trees, and by pruning [illegible] season anyone may see what buds are likely to take the lead. On the other [illegible] with trees from a good source where attention has been given to the [illegible] the trees, there will be little pruning needed save the shortening of a few [illegible] much may eventually be done by pinching the growths in a green state. [illegible] cutting back of newly planted trees, especially stone fruit, soon after planting [illegible] gumming, and at times the shoots or branches die back a long way. Trees [illegible] make a gross growth the first season owing to the check caused by removal, [illegible] if cut now the back buds will soon break. With wall trees, I am aware, it [illegible] necessary to use more judgment in the selection of leaders if the trees are [illegible] large, but even then if necessary to cut harder back it will benefit the trees [illegible] work is done now. For all newly planted fruit trees March and April are [illegible] months, as, owing to the prevalence of east winds, the trees, if at all [illegible] roots, suffer and the bark shrivels; this should be prevented as far as possible or it will produce canker and decay. It is, therefore, well at this date to renew the mulch, and under walls it may be necessary even to give moisture to promote new root action. Much may be done to assist the trees by gently dewing them over early in the day and again directly the sun has left the skies if the growth is at all backward and the bark inclined to shrivel. All staking of trees in the open should now be completed; the ties must not be tight enough to cut the bark, nor loose enough to allow the tree to work loose in the soil. We have just finished making the borders of wall trees neat for the season by giving a top dressing, it is well to keep in view that raised bordersin very light soils dry quickly, our fruit borders are slightly lower than the borders in front and so the moisture does not run away so quickly. Cherries and apricots suffer more from drought than apples and pears, indeed peaches and nectarines may be included when the fruits are swelling freely. Drought is frequently the cause of aphis attacking the trees so early in the season. No time should be lost in giving trees which last year were infested with mealy bug a thorough cleansing, and this can be done now, before the leaves appear, to better advantage. In the case of young trees I have found it well to paint the wood with soluble petroleum.—G. WYTHES, *Syon Gardens.*

THE DARLING DAFFODIL.

THE daffodil figures much in English poetry. One likes Quarles's gay name for her, "the gilt-bowl daffodilly." She occurs exquisitely in Marvell, in one of the most liquid and dewy-fresh poems of the language:—

> "I am the mower Damon, known
> Through all the meadows I have mown.
> On me the morn her dew distils
> Before her darling daffodils;
> And if at noon my toil me heat
> The sun himself licks off my sweat.
> While going home the evening sweet
> In cowslip-water bathes my feet."

Nor must Drayton be forgotten, and his delicious pastoral, in which Daffodil is a maid—"in a frock of Lincoln green." But the poets are full of her.

Her name is beauty itself. If you think on it the English names of flowers are as near like to flowers as possible in nearly every case. She is supposed to derive her name from asphodel, which the old writers often call affodyl. They were like the peasants of to-day in giving even slightly resembling flowers the same name. Gerard speaks of her as daffadowndilly, and Lyte dubs her "yellow crowbels." The supremely happy namers of flowers of long ago gave her no prettier title among many than Sweet Nancy.

Spenser speaks of the daffodils being used for wreaths and garlands, and says Lyte:—"Besides the ornamental use of daffodils in decking garlandes and houses in spring time, the plant hath many physical properties. When the root was mixed with honey and applied as a plaster, it cured aches, pains, and strains. When eaten or drunk (an infusion of it) it helped coughs and colics, and mixed with vinegar and nettle-seed it was used as a cosmetic, breaking away spots from the face."

An old poet talks of Narcissus being turned into "a withered daffodil," but though narcissus and daffodil are sisters, the daffodil is not the beautiful youth, but the Poet's Narcissus. Hear a Scotch poet of the sixteenth century, Alexander Scott, usher in Spring:—

> "The cushet croods, the corbie cries,
> The cuckoo couks, the prattling pies
>   To geck there they beginne;
> The jargon of the jingling jays,
> The crocking craws and keckling kays,
>   They deav'd me with their dinne.
> The painted pawn with Argus eyes
>   Can on his May-cock call,
> The turtle wails on withered trees,
>   And Echo answers al.
> Repeating, with greeting,
>   How faire Narcissus fell
> By lyeing and spying
>   His shadowe in a well."

It was the Poet's Narcissus that Proserpine let fall from Dis's [illegible] being the last she had gathered, it has been accounted by the [illegible] flower of imminent death.

But the association of the narcissus with death comes not only from the [illegible] youth and the daughter of Ceres, but, as Gerard tells us, "Sophocles [illegible] narcissi the garlande of the infernal gods, because they that are departed [illegible] with dethe, should worthily be crowned with a dulling flower." [illegible] of the herbalists assure us that the scent of the narcissus causes a [illegible] may be fatal.

The Fates wore wreaths of narcissus about their heads. Europa [illegible] nymphs, plucked the narcissus:—

> "That wench with these this wench with those
> Trim flowers themselves did all delight.
> She with Narcissus good in scent,
> And she with the Hyacinth content."

In Devon, different varieties of the single white narcissus are [illegible]minately as gooseflaps, gracie and goosie daisies, Lent-pitcher, [illegible] and—a theft from the cowslip—tosty-toss. The double yellow and white [illegible] are butter and eggs and curds and cream. The double white in [illegible] Lady's ruffles, a name shared with a double campanula. The cup [illegible] thought to contain the vain tears Narcissus shed.—*Pall Mall* [illegible]

EXHIBITIONS AND MEETINGS.

ROYAL HORTICULTURAL SOCIETY, March 22.

Once again we have to record a first-rate show at the Drill Hall, for the meeting was a very full one, and practically all the space was occupied. The R.H.S. council will soon have to seriously consider the advisability of renting a larger hall at the present rate of progress. Novelties were not very plentiful, but there was a fair number of interesting plants on view.

Floral Committee.

Groups of considerable size were arranged all round the hall and along the ample tables; daffodils, roses, amaryllis, ferns, hyacinths, and clivias were the most prominent subjects on view; but of these the roses were the most admired, especially the long-stemmed blooms staged by Mr. G. Mount, and the fine specimens from Messrs. W. Paul and Son.

An extremely pretty exhibit came from Messrs. J. Laing and Sons, Forest Hill, and consisted of bouquets, sprays, chaplets, and other floral arrangements of a high order of merit; orchids and roses were largely used, the white Cœlogyne cristata being finely represented. Mr. G. Mount, Canterbury, staged a grand lot of rose blooms, sweet, fragrant, full and brilliant; Captain Hayward, Catherine Mermet and Mrs. W. J. Grant, and Mrs. J. Laing were especially beautiful. Some ten dozen splendid flowers were staged by Mr. Mount, many on tall stems, and the exhibit was greatly admired, both for the earliness of the roses and the cultural ability displayed by Mr. Mount. Messrs. J. James and Son, Farnham Royal, showed a fine group of their splendid strain of cinerarias; the plants were remarkably dwarf, and each had immense flowers showing a charming variety of colours. Some of the blooms must have measured nearly five inches across. From Messrs. W. Cutbush and Son, Highgate, came a display of the yellow Richardea Elliotiana, acacias, Souvenir de la Malmaison carnations, and other flowering and foliage plants, including a number of well-grown examples of Thyrsacanthus rutilans. Mr. W. Rumsey had a large display of roses, staging in the aggregate some fourteen dozen blooms of good quality; the principal varieties on view were Souvenir d'un Ami, Maréchal Niel in quantity, Niphetos, Beauty of Waltham, Innocente Pirola, and the new h. p. Mrs. W. Rumsey.

Mr. A. Chapman, gardener to Captain Holford, Westonbirt, Tetbury, staged a really grand lot of amaryllis or hippeastrums, the plants were strong, and bore stout spikes of large and brilliant blooms of fine shape. A goodly number were named, and these compare very favourably with any previously seen at the Drill Hall. The arrangement of the groups was also good. Tulips in great variety came from Messrs. R. and G. Cuthbert, Southgate: this was a big exhibit, and all the leading early sorts were represented; the Pottebackers, the Keizer's Kroon, Ophir d'Or, Joost Van Vondel, and Toreador were especially attractive and noteworthy. Mr. H. B. May, Edmonton, once again showed clematis in small pots, handsomely flowered, and eminently suited for conservatory decoration. These were arranged with ferns and palms, but the place occupied by the group was not a good one as regards light; Henreyi, Lord Lonsdale, Lord Neville, Albert Victor, and Fair Rosamond were conspicuous varieties. Daffodils in pots from Mr. T. S. Ware made up a telling exhibit, and were fronted with erythroniums, fritillarias, muscaris, trilliums, early primulas, saxifragas, and other early spring flowers. Bunches of the earlier daffodils were also arranged. Messrs. J. Laing and Sons, Forest Hill, put up a large exhibit of flowering and foliage plants; clivias, streptocarpus, azaleas, Leea amabilis, Richardia Elliotiana, caladiums, and crotons were the most conspicuous and interesting plants. Messrs. J. Hill and Son, Lower Edmonton, put up a fine lot of ferns, mostly popular varieties and species—adiantums, aspleniums, nephrolepis, &c.; both small and large specimens were staged, and the whole display proved a most refreshing contrast to the brilliant groups around.

A wonderfully interesting group of clivias came from Messrs. J. Veitch and Sons, Chelsea; these were remarkable for the size and boldness of the trusses and the brilliant colour of their large and substantial flowers. Several of the varieties gained awards of merit, one in particular, which had flowers of quite a yellow colour, was very beautiful; Optima has huge orange flowers. The group was effective in the extreme. The Messrs. Veitch also staged Clematis Marcel Moser, and C. Nelly Moser, two handsome striped forms, also baskets of Shortia galacifolia and flowering trees of Pyrus floribunda atrosanguinea. A batch of the brilliant winter scarlet carnations was staged by Messrs. H. Low and Co., Clapton. Hippeastrums and clivias in variety came from Messrs. B. S. Williams and Son, Holloway, and the same firm showed a splendid lot of varieties of Azalea mollis. Messrs. Barr and Sons' contribution to the show consisting of a first-rate exhibit of narcissi, all cut blooms; Madame Plemp, Empress, Obvallaris, Weardale Perfection, the New Victoria, Mrs. Walter Ware, Captain Nelson, Madame de Graaff, and Glory of Leiden were all the very best varieties, and staged among a large collection of early-flowering forms; a few blooms of Anemone fulgens further lengthened the exhibit. Messrs. Paul and Son, Cheshunt, exhibited large pans of Megasea Stracheyi, Primula denticulata, Anemone Pulsatilla, Hepatica tricolor, &c., all being in full flower. Mr. J. Heath, gardener to J. Watts, Esq., Newmarket, staged a batch of wallflower, a form that may prove useful for bedding. Cinerarias of good quality came from Mr. J. R. Box, Croydon, and drew many expressions of admiration from the visitors by reason of their beauty of form and colour.

Messrs. W. Paul and Sons, Waltham Cross, have not for a long time been public exhibitors of hyacinths, and it was quite a treat to see a firm that formerly made a great name for these bulbous plants once again before the public with a splendid collection of some two hundred specimens in a large number of varieties. Sterling Beauty, yellow; Pelissier, scarlet; Princess Amalie, white; Vurbaak, red; Lady Derby, pink; King of the Blacks, very deep in colour; Peineman, blue; and Princess Mary of Cambridge, light blue, were a few remarkable for the length and breadth of their spikes. Messrs. W. Paul and Son also showed a fine bank of roses, all new varieties: Enchantress was in fine condition, and represented by two large groups; other new sorts were Auguste Riviore, Sylph, Souvenir de Madame Eugene Verdier, and Charlotte Guillemot. The Jadoo Fibre Company made an exhibit of plants grown in the fibre, and some of the plants were grown in glass pots to show the way roots take to this new medium. The St. George's Nursery Company, Hanwell, staged a splendidly-grown group cyclamen, representing a high-class strain.

Orchid Committee.

It is a long time since there were so few orchids at a Drill Hall meeting as on this occasion. There were several good novelties, however, and these excited no small interest.

Mr. W. A. White, orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, brought up a few neat little plants of Epidendrum Endresi, E. varicosum, Sarcochilus Hartmanni, and Masdevallia Pourbaixi. Messrs. Hugh Low and Co., Clapton, were the only large exhibitors of orchids, and they staged a handsome lot of odontoglossums and dendrobiums, with several beautiful forms of Cattleya Mendeli, some cypripediums and lælias. Phalænopsis Stuartiana var. punctatissima was also shown, and is a distinct form of a fine orchid.

Mr. H. T. Pitt, Stamford Hill, gained a cultural commendation for a plant of Odontoglossum excellens Rosslyn var., a beautiful orchid, with ten large flowers on the spike. Mr. J. T. Gabriel, Streatham Hill, sent a good form of Cattleya Trianæ. Mr. Ballantine, gardener to Baron Schröder, The Dell, Egham, exhibited Odontoglossum crispum Princess Christian, a handsome form, with crimson markings on a pure white ground. Mr. Wise, gardener to Dr. F. Hills, Croydon, sent a flowering specimen of Odontoglossum coronarium. Mr. E. Ashworth, Harefield Hall, Wilmslow, sent a fine white form of Dendrobium nobile, named D. n. Ashworthiana, and also a hybrid odontoglossum in the way of O. Rossi and O. aspersum, named D. hybridum Ashworthianum. Mr. Standing, gardener to Miss Ford, Worthing, sent Cymbidium Lowianum and a three-flowered spike of C. eburneum.

Frau Ida Brandt sent a form of Oncidium cuculatum Phalænopsis, remarkable for its rich purple markings. Messrs. B. S. Williams and Son, Holloway, were accorded a vote of thanks for a small collection of orchids, in which cœlogynes, dendrobiums, and cypripediums predominated. Mr. T. Rochford, Broxbourne, sent a pretty brown spotted odontoglossum, named provisionally O. Rochfordianum. Odontoglossum crispum roseum was shown finely by Mr. J. Drew, gardener to J. B. Brookes, Esq., Finstall Park, Bromsgrove.

Fruit and Vegetable Committee.

Extremely few exhibits came before this body, so that their labours were few. In fact, Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, was the only exhibitor apart from the competitions. Mr. Wythes won a cultural commendation for half a-dozen punnets of Royal Sovereign; fine fruits and well coloured.

Mr. J. C. Tallack showed the best-flavoured apple in Lamb Abbey Pearmain; Mr. Herrin, Dropmore, second, with Sturmer Pippin. For pears, Mr. Ross, Welford Park Gardens, was awarded a second.

Medals.

Silver-gilt Flora Medals were awarded to Messrs. W. Paul and Sons, for roses and hyacinths; to Mr. G. Mount, Canterbury, for roses; to Captain Holford, for amaryllis; to Messrs. J. James and Son, for cinerarias, and to the St. George's Nursery Company for cyclamen.

Silver Flora Medals were awarded to Mr. W. Rumsey, for roses; to Messrs. J. Veitch and Sons, for clivias; and to Mr. H. B. May for clematis.

Silver Banksian Medals were awarded Messrs. J. Laing and Sons for clivias, wreaths, &c.; to Messrs. Hill and Son, for ferns; and to Messrs. Hugh Low and Co. for orchids.

NATIONAL CHRYSANTHEMUM SOCIETY, March 21.

The adjourned annual meeting of this society was held at Anderton's Hotel, Fleet Street, on the above date. The hour for commencing should have been six o'clock, and by that hour a large number of members had gathered, but could not obtain admittance until twenty minutes later, owing to the lengthy deliberations of the committee. After the notice of the meeting had been read, the meeting was resumed with Mr. T. W. Sanders in the chair.

Mr. B. Wynne opened the proceedings by drawing attention to a remark made by Mr. Gordon when discussing the finance of the society, wherein he stated in effect that medals had been voted to certain officers of the society at a time when the society could not afford it. As the recipient of one of the medals Mr. Wynne felt rather hurt at the remark, and he asserted that he had had no idea of the society's position when the medals were presented. Any pleasure he might have had in possessing the medal had now been entirely discounted, and he begged to return the medal, for which he had no further use. In reply, Mr. Gordon said that the set of medals, in which Mr. Wynne's was included, were paid for in a previous year to that they had been discussing, and so they had no power to deal with them; he, however, did not have the Jubilee medals in his mind when discussing finances, but rather the presentation of gold medals and costly illuminated addresses on a more recent occasion. He hoped that Mr. Wynne would retain the medal, for with it went the best wishes of the society. The explanation was received with applause, and Mr. Wynne was loudly applauded upon again resuming possession. The minutes of previous business were then accepted with a slight emendation. Mr. Fife proposed the adjournment of the meeting for twenty-four hours, because the chairman was the chairman of the Executive Committee, whose methods of management they were come together to discuss. If the meeting, however, would promise to assist the chair, and if it believed in the impartiality of the chairman, then he would withdraw his motion. The motion was withdrawn, and the chairman proceeded by formally moving the adoption of the revised financial statement. This was seconded, and then Mr. Cholmeley asked why there were no signatures of the auditors to the new statement of accounts; the reason of a small difference in the reserve fund, allowing for the withdrawal of a certain sum; and whether it was true the treasurer had not received or disbursed the society's moneys, and if so, whether there was any need to elect a treasurer in future. Mr. Pearse asked why bill posting appeared on both sides of the accounts. The Chairman, as an answer to Mr. Cholmeley, read a letter from the auditors, in which they stated that having once audited the accounts and found them correct, and in accordance with vouchers produced, they had performed their duties, and so did not feel at liberty to attach their names to a further statement, and one not made by them. They further asserted that at the audit they had no knowledge of any liabilities of the society, and they had not been asked to value the society's assets. Messrs. Cutbush and Stubbs, both of whom were present, held to the statements made in their letter.

Mr. Dean followed with an explanation by the item of show expenses previously objected to, and stated that he had always endeavoured to reduce such expenses, as a careful examination of the accounts would show. These figures have already appeared in our columns. Mr. Moorman objected to references to old methods of management, and said, so far as he could see, the show expenses were £102. He considered that the business of the society had not been properly conducted; balances to the good had been shown, whereas, at the same time, the society was really considerably in debt. The medal and printing accounts were too large, and he thought tenders for these should be asked for. He strongly objected to selling the ground floor space at the Aquarium for miscellaneous exhibits, and placing the real exhibits of the N.C.S. in the dark galleries. The annual dinner account he thought far too high, and strongly opposed the presentation of tickets for that function to the daily press. Mr. Dean said Mr. Moorman's assertion as to show expenses was a reckless one, for £50 of the sum was for postage and telegrams, chiefly incurred in sending out the schedules, medals, and certificates to affiliated societies, replies to entries, &c.; these expenses could not justly be lumped with the other show expenses. Mr. Moorman's reply was that "Petty cash—stamps, telegrams, &c.", appeared in the accounts, and he naturally inferred that petty cash was the largest item of the £50 15s. 10d., and so ought to go as show expenses.

Several other members having spoken, Mr. Starling explained his position as treasurer; he had known that debts had accumulated from year to year, although the accounts showed a balance in hand. He had told the society he had such knowledge, and had, time after time, asked the members to appoint a treasurer having full powers of that office. So far as the accounts they saw were concerned, they were correct. He considered that a national society should have a reserve fund, and properly balance its accounts year by year. He had instituted the reserve fund, but now he did not feel able or justified in assisting a national society as he had done its local progenitor. If there was any blame he would accept it, for he had neither time nor health to enter into all the work and difficulties arising out of the office. He, however, had discussed the finances because he had finally concluded to resign office, and he did not wish the incoming treasurer to experience the difficulties he had. There were no outstanding liabilities, and though they had no balance in hand to start with there were fifty odd pounds to fall back upon. Mr. McKerchar observed that if the treasurer or other officer of the society had any doubts as to the correctness of accounts they should have placed all such doubts before the society. Then also all liabilities incurred in each year should be met the same year, so that at the annual meeting everyone would know the precise condition of affairs. Mr. Willis wished to know whether he was to understand that the auditors did not know of liabilities outstanding when auditing the accounts? It was shown by the letter read that they had had no such knowledge. Mr. Willis thought this could not have been, seeing that in the financial statement audited and presented February 28 some items showed that certain bills were but paid in part. Others joined in the discussion, notably Messrs. Mills, Spicer, Waterer, Newell, Gordon, Tagg, Cannell, and Bevan. Mr. Starling asserted that the auditors did know of outstanding liabilities, or should have done, by reason of certain payments on account. There were cries of "Vote!" and the result was a passing of the revised financial statement, though not unanimously.

The report then came on for discussion, after its adoption had been moved by Mr. Sanders, and seconded by Mr. W. Beckett, but a proposition by Mr. Moorman that the estimated receipts and expenditure for the ensuing year be first considered was carried. Mr. Dean then read the estimates, containing the minimum of subscription and a maximum of expenditure: Receipts, £1,066 11s.; expenses, £1,115 1s. 6d.; result, a deficit of £48 10s. 6d. Since this estimate had been drawn up, the Secretary informed the meeting, the Schedule Sub-committee had reduced the amount of prizes and expenses, this bringing the total expenditure down to £1,044 3s., and thus leaving a balance in hand of £22 8s. These estimates having been accepted, the report was discussed. Mr. Moorman moved that in the first paragraph the words relating to resources, finance, supporters, and prestige be deleted, as these could scarcely be reconciled with what had already happened. Mr. Beckett and Mr. Willis supported Mr. Moorman. Messrs. Taylor and Ballantine considered the report a correct one. Mr. Moorman differed, and did not consider that the society was financially sound after a loss of £70 on the year's working, or its resources as great as ever when about half the reserve fund had been used up. Mr. Cholmeley opined that the words in question were unnecessary, but if the report was altered, it would fail to be that of the committee. Mr. Moorman's amendment having been put and rejected, Mr. Addison moved that with the deletion of Paragraph 8 relating to the increase of prizes the report be adopted. This was put and carried, and so the report was passed.

Votes of thanks were then accorded to the auditors, and to the president; and Sir Edwin Saunders was unanimously re-elected president, on the motion of Messrs. Cannell and Langdon. The next item was the formal acknowledgment of the treasurer's resignation, and a recommendation of the committee that Mr. Starling be made an Honorary Fellow of the N.C.S., and receive a small gold medal and a letter of thanks for his past services to the society. Mr. W. Beckett moved that this be done, and Mr. Ballantine seconded the motion, adding to it, That the letter of thanks be engrossed on vellum. The motion was carried, and Mr. Starling feeling responded. The re-election of Mr. T. W. Sanders as chairman of committee was proposed by Mr. G. Gordon, who alluded to the good work Mr. Sanders had accomplished; Mr. Waterer seconded, and said he himself would accept the position of vice-chairman, only on condition that Mr. Sanders occupied the chair. Mr. Sanders was unanimously re-elected to the chair, and Mr. Waterer to the vice-chair. Previous to the election of secretary, Mr. Moorman proposed and Mr. Rundle seconded that the society have a paid secretary, and that such official have no vote; this was carried unanimously. Messrs. Bevan, Wells, and Mills raised questions as to salary and advertising for a secretary, but the Chairman pointed out that under the rules the secretary had to be elected by the annual meeting, or a special general meeting. Five scrutineers having been appointed, the meeting proceeded to elect a treasurer, a secretary, and thirteen members of committee. There was a heavy poll, and it was found that Mr. Ballantine had been elected treasurer. Messrs. Dean and Cummins were nominated for the post of secretary, the former winning with 63 votes; Mr. Cummins, 43. The committee-men elected and the votes accorded were: Mr. T. Bevan, 94; Mr. G. Langdon, 78; Mr. A. Taylor, 77; Mr. W. Howe, 70; Mr. W. Wells, 63; Mr. Kendall, 59; Mr. W. Higgs, 59; Mr. T. L. Turk, 56; Mr. J. T. Simpson, 56; Mr. W. Daniels, 53; Mr. F. Gilks, 51; and Mr. Fife, 44. Messrs. A. Outram and Rowbottom having each gained 43 votes, it was decided by a show of hands that Mr. Outram be elected. Twenty-seven members were nominated as committee-men.

After waiting a considerable time for the result of the poll, the Chairman proposed that the meeting proceed with the new rules. He earnestly requested that all should remain and discuss whatever they thought necessary, and not leave the responsibility of passing the new rules to a few. He also appealed to the members to assist him by orderly conduct, brief speeches, and keeping to the question before the meeting, and conduct the remaining business as quickly as possible. The chairman then formally moved that the old rules be rescinded and the new ones substituted; this was seconded by Mr. H. J. Jones, and the meeting then, taking rule by rule, agreed to them in the main, though several amendments of varied importance were made as the work proceeded. At eleven o'clock Mr. Moorman moved that the meeting be adjourned for a fortnight, but this motion was rejected. Finally, at twenty-two minutes past eleven, the meeting concluded with a vote of thanks to the chairman, and the election of Mons. E. Calvat and Mr. Starling to Honorary Fellowships.

Those who took part in the discussion of the new rules were Messrs. Cholmeley, Moorman, Fears, Rundle, Woodason, Wynne, and Dr. Gorton. We have not space to give the amended new rules, but they will soon be in the hands of members. However, it may be stated briefly that in future delegates from affiliated societies will have, unquestionably, the power to vote and otherwise act as committeemen. Subscriptions in future will be due on January 1 instead of March 1, and the accounts will be balanced on December 31 of each year; also in future the annual meeting of the society will be held on the first Monday in February. The secretary will not act as show superintendent except by order of the committee. There are nineteen rules now, and these are really [illegible] ones revised, emended, and brought up to date, so as to be less cumbersome [illegible] the old ones. Messrs. Cholmeley and Stubbs are auditors for the ensuing year.

READING GARDENERS' ASSOCIATION.

"COMMON Mistakes in Fruit Culture" was the subject of an excellent [illegible] tical and instructive paper given by Mr. George Bunyard, of Maidstone, [illegible] Reading and District Gardeners' Mutual Improvement Association [illegible] evening last in the Club Room, British Workman. Mr. C. B. [illegible] over a large attendance of members, including a contingent from the [illegible] Gardeners' Association. Mr. G. Bunyard, in introducing his [illegible] his reason for taking up this particular one was that he, as an expert, had been very often called in to report on certain failures in fruit culture, and that if these failures were embodied in a sort of talk together it would, he felt, be practical, as well as being profitable to each one. The whole routine of the cultivation of apples, pears, peaches, nectarines, gooseberries, and similar fruit was touched upon, including planting, the cropping of the fruit borders, summer pruning, [illegible] pruning, soils, labelling, importance of the early thinning of fruit, ingathering of the fruit, fruit trees in pots, grafting old trees, artificial manures, obtaining [illegible] true to name, differing seasons, and the literature of the day as regards [illegible] culture.

The paper was followed with the closest attention, and at the close many questions were asked and an interesting discussion took place, in which Messrs. Parfitt, Martin, Turton, Webb, Woolford, Neve, Hobbs, and Hinton took part. At the close a very hearty vote of thanks was accorded to Mr. Bunyard by the members, as well as their congratulations on his and his family's escape from the terrible epidemic that had so recently visited his neighbourhood. A great feature of the meeting was the magnificent exhibit of orchids made by Mr. Woolford, gardener to Alfred Palmer, Esq., of East Thorpe, including some splendid [illegible] of Dendrobium nobile and D. Wardianum, two specimens of the latter, in [illegible] pans, carrying eighty to seventy-eight blooms. On behalf of the members the president tendered to Mr. Woolford their thanks for the trouble he had taken in bringing such a fine exhibit to the meeting, especially with regard to Dendrobium nobile, as at their last meeting a controversy had arisen as to the advantages and disadvantages of pruning D. nobile. Mr. Bright, of Whiteknights Park Gardens, showed a splendid head of a new clivia, and Mr. Neve, of Sindlesham [illegible] Gardens, varieties of apples.

NEW PLANTS AND FLOWERS.

ODONTOGLOSSUM CRISPUM PRINCESS CHRISTIAN.

THIS is a most handsome odontoglot, having large and prettily-spotted blooms. The flowers are pure white, and the petals have fringed margins. All the segments are pointed, and the petals have a few large blood-red spots, but the sepals have both spots and blotches of this intense colour. Each flower is [illegible] inches across, and a dozen were borne on a spike. F.C.C., March 22. [illegible] Ballantine, gardener to Baron Schröder, The Dell, Egham.

ODONTOGLOSSUM HYBRIDUM ASHWORTHIANUM.

A most curious orchid, having O. Rossi, or a form of that species, as one parent. The sepals are narrow, very dark brown on a green ground. Petals bright rosy purple with brown spots at the base. The cordate lip is bright rose. A.M., R.H.S., March 22. Mr. E. Ashworth, Harefield Hall, Wilmslow.

DENDROBIUM NOBILE ASHWORTHIANUM.

This is a pure white-flowered dendrobium, and as much like a form of D. [illegible] as of D. nobile. The committee, however, passed it as a D. nobile form. The sepals and petals are slightly twisted and of a transparent whiteness; [illegible] broad and creamy white; the latter is also broad. F.C.C., R.H.S., March [illegible] Mr. E. Ashworth, Harefield Hall, Wimslow.

ODONTOGLOSSUM HYBRIDUM ROCHFORDIANUM.

A most interesting odontoglossum, that seems to have a close affinity with [illegible] Hunnewellianum. The blooms are about an inch and a half across; the petals are creamy, with red-brown spots; the sepals are creamy with a brown tint and heavy blotches and spots of red brown. A.M., R.H.S., March 22. [illegible] Rochford, Turnford Hall Nurseries, Rochford.

CLIVIAS.

Optima has very large blooms from three to four inches across, and of a [illegible] orange colour; the bases of the segments are of a yellowish hue.

Favourite. This variety is most distinct, the trusses large, and the flowers of full size but of a rich yellow shade, faintly tinged towards the apices of the segments with orange. Both the foregoing gained an A.M., R.H.S., March 22. Messrs. J. Veitch and Sons, Chelsea.

HYACINTH CITY OF HAARLEM.

A beautiful single-flowered hyacinth producing a splendid spike of large bells of a very light but telling buff shade. A very fine hyacinth and most distinct. A.M., R.H.S., March 22. Messrs. W. Paul and Son, Waltham Cross.

DRACÆNA EXQUISITE.

A handsome dracæna with leaves three inches across, and about fifteen inches long; these are deep green with creamy margins to the young foliage, and [illegible] margins to older leaves. Many of the leaves are finely-coloured with bright [illegible]. This should prove useful as a vase plant, and for similar purposes. A.M., R.H.S., March 22, Messrs. J. Veitch and Sons, Chelsea.

HIPPEASTRUMS.

Beacon is a gorgeous variety with rounded flowers of the richest crimson [illegible]. All the segments are of immense breadth and substance. A.M., R.H.S., March 22. Mr. Chapman, gardener to Captain Holford, Westonbirt, Tetbury.

Clonia, a very pretty form with a creamy-white ground colour, feathered with scarlet towards the edges and tips of the segments.

Tacola, a round orange-coloured form, the colour varying in shade. Over the centre of end segment is a broad white band.

Ideala has a white ground colour, and over this are shadings and splashes of deep orange-scarlet, especially marked towards the apices. A fine bold form. The three foregoing each gained an A.M., R.H.S., March 22. Messrs. J. Veitch and Sons, Chelsea.

AZALEA JAPONICA RUBRA.

A pretty azalea with crowds of small and rich scarlet-red flowers on all the slender growths. It has a bushy habit, and in shape the flowers are not unlike those of Azalea amœna. Mr. W. Smythe, gardener to W. Nicholson, Esq., Basing Park, Alton.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. [illegible] "Gardeners' Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forth coming exhibitions and meetings, and are requested to advise us concerning change of dates.

Gasoline Motor Lawn Mower.—C. D., Newbury: We are at present unable to give you the address of the makers of the Motor Lawn Mower illustrated recently in our columns. It is an American invention.

Botanical Magazine.—W. P., Dursley: The volumes referred to by our correspondent W. T., Cowes, were some of those issued during the first twenty years of the *Bot. Mag.* The volumes you mention are among the most expensive of the whole set.

Curators of London Parks.—E. S., Kew: The addresses you need are—Mr. W. Browne, Superintendent, Hyde Park, W.; Mr. F. J. Coppin, Superintendent, Battersea Park, Battersea. Kensington Gardens are under the same management as Hyde Park.

Oncidium sphacelatum.—P. S. T., Hull: This is an easy orchid to cultivate, and one that is frequently seen growing and flowering freely when treated as an ordinary stove or intermediate house plant. If, however, your specimen is not in the best ot health, it will need careful treatment. Directly new growths commence to push and new roots to form is the proper time to repot or top-dress the plant, using a compost of fibrous peat and sphagnum, with ample drainage below. As the species likes warmth more than most oncidiums, it may with advantage be placed in a warm house during the period of active growth; after the growths are completed, stand the plant in a cooler and dryer position, such as a greenhouse or vinery, and give less water. Water must not be wholly withdrawn, as the species objects to anything like drying off. A strong specimen in full growth will stand syringing frequently; indeed, owing to the progression of growths some become so placed that their roots do not soon reach the soil, consequently syringing is almost necessary. It will probably be best to break up your plant to ensure a good and clean start.

Cypripedium Mrs. H. Druce.—We have received from Mr. G. Walker, gardener to H. Druce, Esq., St. John's Wood, the following letter, and desire for correction: "I beg to say that a mistake was made in your report of the R.H.S. meeting of March 8 last, as contained in your issue of March 12, concerning my hybrid, Cypripedium Mrs. H. Druce (C. niveum crossed C. bellatulum). Being the raiser I know the parentage is correct. The foliage is quite distinct from that of C. Godefroyæ; also, the flowers of C. Mrs. H. Druce have a white ground, while in C. Godefroyæ this is yellow." In reply, we have to congratulate Mr. Walker upon having raised a handsome cypripedium between two interesting species. We still hold the opinion that C. Mrs. H. Druce is nothing but C. Godefroyæ artificially produced, and not differing much in any material respect from the latter. It has long been thought that C. Godfroyæ was but a natural hybrid between C. niveum and C. bellatulum, though in some plants the influence of C. concolor instead of C. niveum seemed apparent by reason of the creamy or faint sulphur tinge. Some objection to this origin of C. Godefroyæ as a natural hybrid have been raised, the chief being that of geographical distribution, This objection has been removed by the production of C. Godefroyæ as a result of crossing C. niveum and C. bellatulum, the plant flowering in the collection of G. W. Law-Schofield, Esq., New Hall, Hey, Rawtenstall, of which our coadjutor, Mr. Shill, has charge; the seedling has been generally recognised as C. Godefroyæ. When we consider the variation to be found in C. bellatulum, and in C. concolor, which extends towards the less variable C. niveum, we can understand how the progeny of varied forms of these would also be varied and allow for the present difference found in C. Godfroyæ. Our correspondent states that C. Godfroyæ has yellow-ground flowers; he might with equal propriety have stated they had white ground flowers, for the shade varies from purest white in C. Godfroyæ Gardenianum to primrose yellow in C. Godfroyæ luteum. The form in which C. niveum and C. bellatulum appear most distinctly as parents is known as C. Godefroyæ leuchochilum; others, as noted, appear to be the result of a cross between C. concolor and C. bellatulum, while still others may be the result, and doubtless are, of combining C. concolor with C. niveum. It has been suggested, and with much probability, that the whole group of cypripediums here referred to are but variations from one type and the result of the intercrossing of such variations. However, for the present it is sufficient that C. Godfroyæ has been produced at New Hall, Hey, and at St. John's Wood, by crossing C. bellatulum and C. niveum, so the provisional name of C. Mrs. H. Druce cannot stand, and C. Godefroyæ var. Mrs. H. Druce would be both cumbersome and unnecessary. Mr. Walker has proved both the New Hall, Hey, cross, and opinions long held. The Orchid Committee of the R.H.S. considered the hybrid Mr, Walker has raised to be C. Godefroyæ.

Names of Plants.—P. S. F., Hull: Oncidium sphacelatum. No, the daffodil is not an uncommon form.

H. J., Barton: 1, Chlorophytum elatum; 2, send when in flower; 3 and 4, next week; 5, Pulmonaria officinalis; 6, Thalictrum minus.

S. O., Hampton: 1, Prunus Pissardi; 2, Muscari botryoides; 3, Saxifraga oppositifolia.

N. A. F., Wroxteth: 1, Asplenium Nidus avis; 2, Selaginella Emileana; 3, Choisya ternata; 4, Hibbertia dentata; 5, Eupatorium riparium.

The mean reading of the Barometer during the week at Greenwich was 29·82 inches, and that of the Thermometer 45°·7, the latter being 4°·4 above the week's average in the 50 years 1841—90. The direction of the wind was south-westerly, the horizontal movement of the air being 7 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 13·3 hours. The measured rainfall amounted to 0·25 of an inch.

A GREAT BLESSING TO HUMANITY is without doubt a medicine composed of ingredients that, whilst it eradicates the germs of disease, strengthens the system. Holloway's Pills act in this manner, and in general debility, mental depression and nervous irritability there is no remedy which operates so beneficially. They purify the blood, give tone to the stomach and thoroughly regenerate the system. They are mild in operation, although most powerful in removing disease. Delicate females and young children can take them with safety and benefit. It would be difficult to enumerate all the advantages to be derived by taking these wonderful Pills. No household should be without them, for there is no complaint which they cannot cure or relieve.—[ADVT.]

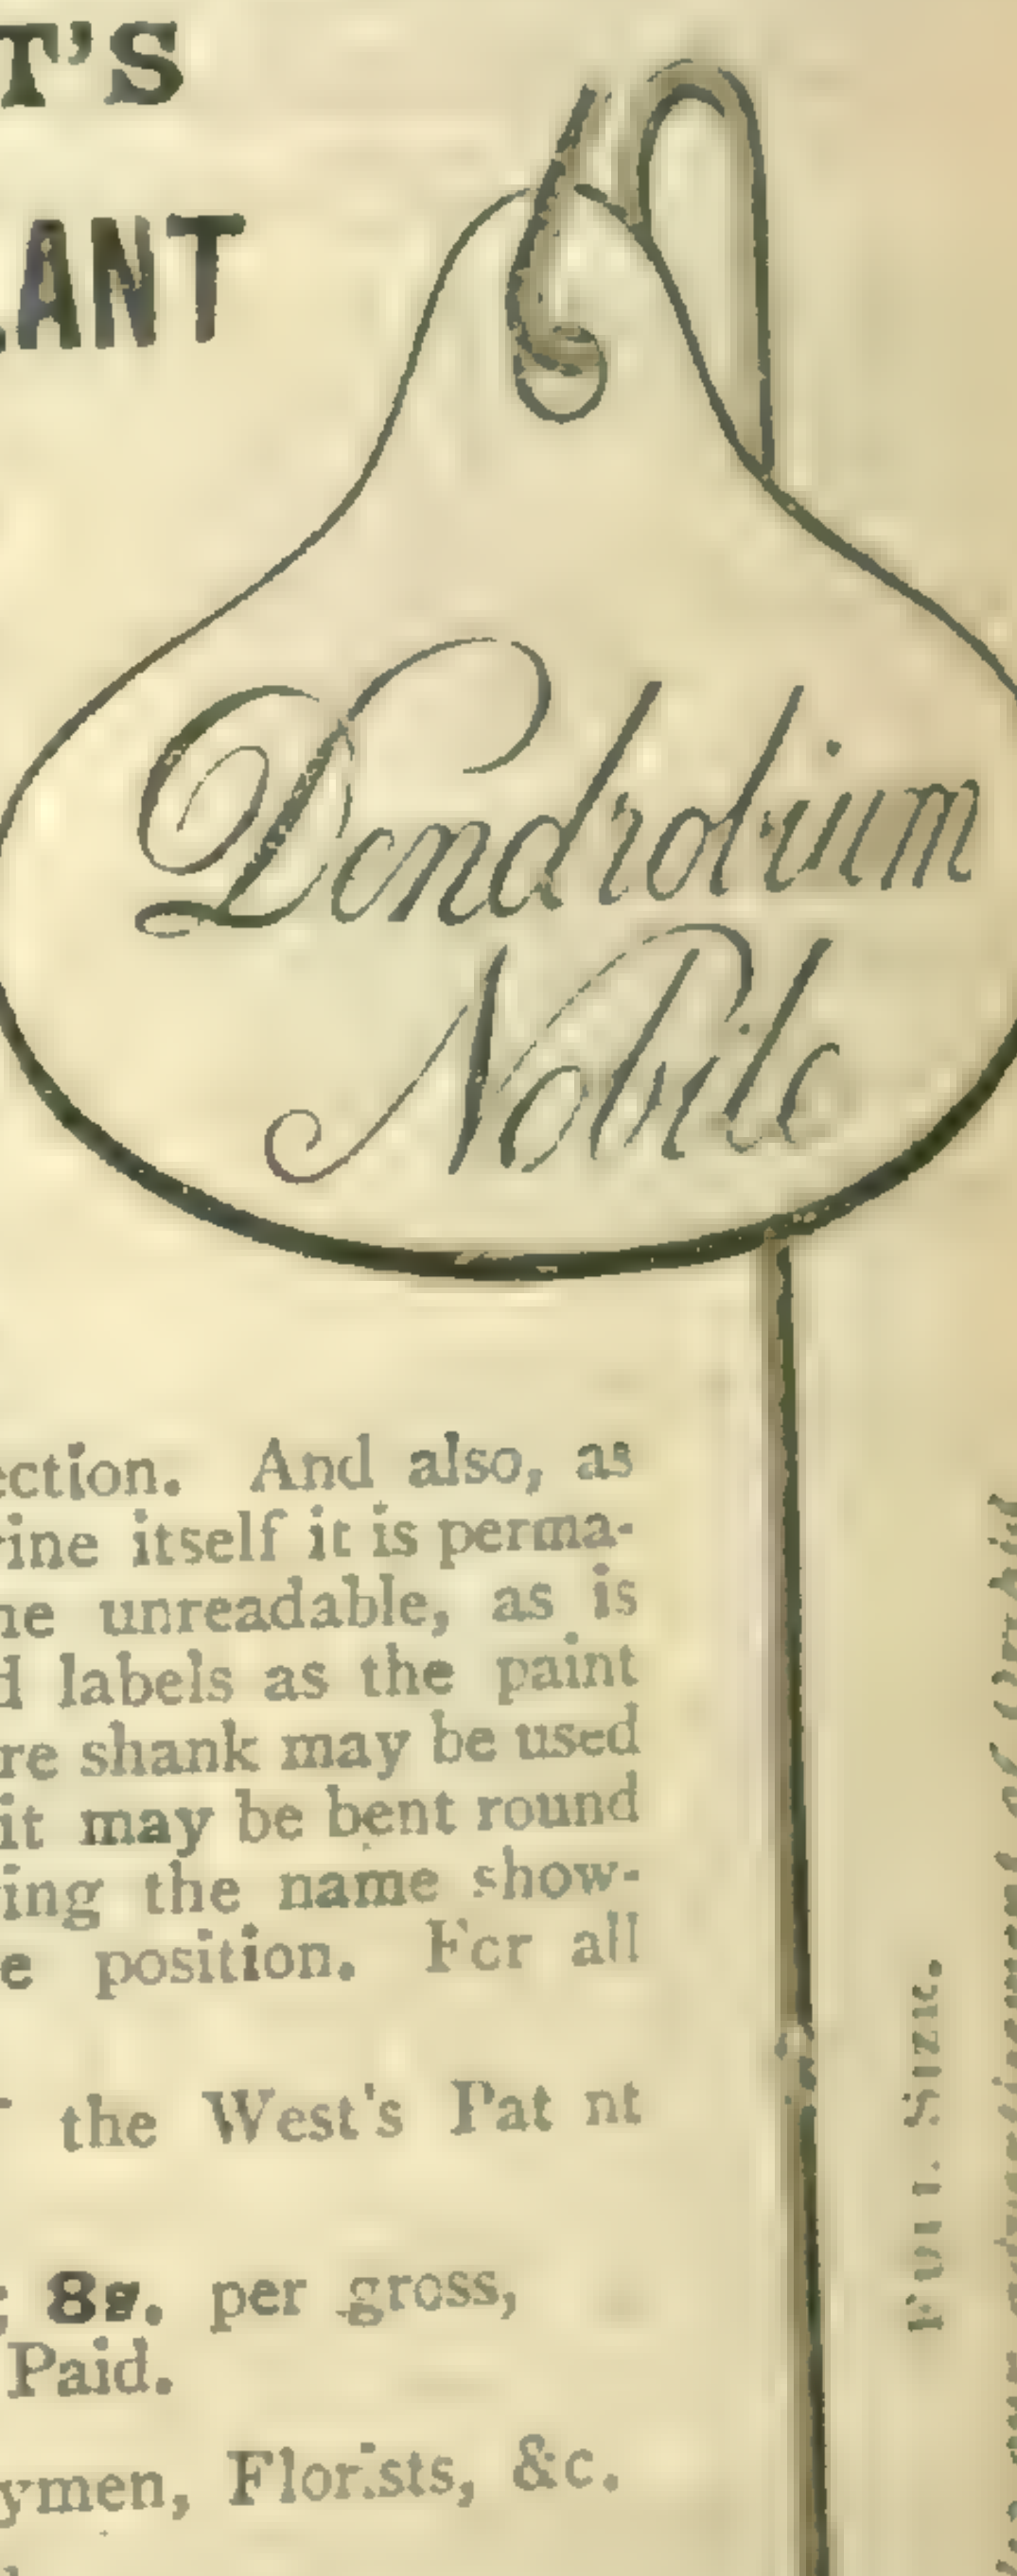
THE WEST'S
PATENT
IVORINE PLANT LABELS.



Dendrobium Nobile
FULL SIZE.
(See also our advertisement of Orchid

The "Ivorine" Writing Disc, which is to be written upon, being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon by a common lead pencil or pen and ink, it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, and does not become unreadable, as is the case with all painted labels as the paint gets old. The copper wire shank may be used as per the illustration, or it may be bent round the stem of a plant, leaving the name showing in the most readable position. For all horticultural purposes.

Samples and Lists of the West's Patent Specialities post free.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

HORNSEY URBAN DISTRICT COUNCIL.

QUEEN'S WOOD, HIGHGATE.

APPOINTMENT OF KEEPER.

The Hornsey Urban District Council REQUIRE the SERVICES of a KEEPER and his WIFE for the Queen's Wood, Highgate.

The wages will be 30s. per week, with Lodge, and until the Lodge is completed and ready for occupation the wages will be 40s. per week.

Applicants must be between 25 and 40 years of age, and preference will be given to those having had previous similar experience and who possess a knowledge of Forestry.

Applications, in own handwriting, containing particulars of past and present employment, with copies of not more than three recent testimonials as to character and competency, marked outside "Keeper, Queen's Wood," must be received on or before the 18th April next, and be addressed to Mr. E. J. Lovegrove, Surveyor, Council's Offices, Southwood Lane, Highgate, from whom printed particulars of the duties can be obtained on application.

By order,
F. D. ASKEY,
Clerk to the District Council.
Offices, Southwood Lane, Highgate, N.,
28th March, 1898.

COMPETITION DEFIED!
OUR UP-TO-DATE SEED CATALOGUE

for 1898 proves that our prices are far below any others. We guarantee our Seeds to be

NEW, GENUINE, and RELIABLE.

In dealing with us great benefit is derived, as we do not spend our clients' money in costly advertisements; nor is our Catalogue a work of art, entailing enormous expense (needless to ask who pays for this). We have shown what we can do in the BULB TRADE on the score of economy and excellence, and we shall supply our Seeds on the same basis. Therefore, send for our Catalogue (free), and judge for yourselves.

CANNELL'S NEW PLANTS.

Of the Highest Importance where PLEASURE and BUSINESS are Desired.

THERE has not certainly, during recent years, been any New Plants offered that have given such satisfaction, and attracted the public eye when exhibited, as the following:—

CHRYSANTHEMUM.—White Mrs. Filkins, the queen of all varieties for cut flowers. Every one now admits the yellow we introduced has proved a most valuable variety. This novelty is pure white, of the exact same exquisite form and character, invaluable acquisition for select decorative purposes, and for buttonholes a gem of gems, 21s. each.

CHRYSANTHEMUM.—Miss Gertie Waterer, loveliest colour, most attractive of all Pompons for cut flowers, 1s. 6d each.

CHRYSANTHEMUM. — Little Dot, quite a miniature gem, the smallest and prettiest yet seen, a new shade of colour, 1s. 6d. each.

DAHLIA, CACTUS.—The Czar, lovely shape, always reliable, brilliant crimson colour, best habit, a gem, 7s. 6d. each.

DAHLIA, LORELY.—Cactus-shape, of the most delicate La France Rose colour, a decided improvement, best of its colour, 3s. each.

DAHLIA.—Orange, Glare of the Garden, a bright orange-yellow scarlet Glare of the Garden or Fire King, for general cut flower purposes. This is by far the most useful, as valuable in its way as White Mrs. Filkins, 7s. 6d. each.

FUCHSIA.—Addington, a perfect hybrid, a cross between fulgens and cordifolia; profuse flowerer, strong grower, one of the prettiest of all the family as a pot plant ever seen. An Award of Merit R.H.S. 7s. 6d. each.

TROPÆOLUM PHŒBE.—A new shape and distinct colours, deliciously scented, and as a climber indoors during the spring and outdoors in summer it gives a new feature. 1s. each. An Award of Merit R.H.S.

WITHANIA ORIGANIFOLIA. — The Pampas Lily of the Valley, a perfectly hardy Climber, and a most rapid-growing plant, somewhat like the common Tea-tree, producing an innumerable quantity of white, bell-shaped flowers; equally as suitable in smoky towns as in the country. 1s. 6d. each.

ZONAL PELARGONIUMS.—Our set of these are the most distinct and beautiful that we have had the honour of introducing. For full particulars of these, and all the above, see our ILLUSTRATED and DESCRIPTIVE FLORAL GUIDE, which will be found the very life and success of every gardener; post free to coming customers.

H. CANNELL and SONS,
SWANLEY, KENT.

5,000 GRAND NEW STRAWBERRY MONARCH, 7s. per 100, 50s. per 1,000. NEW ASPARAGUS, Barr's Mammoth, 2 years, 4s. per 100, 35s. per 1,000. Connover's Colossal, 2 years, 3s. per 100, 20s. per 1,000; 3 years, 30s. per 1,000. Apple and Plum Grafts in great variety. —W. HORNE, Cliffe, near Rochester.

MACMILLAN & CO.'S New and Recent BOOKS ON GARDENING.

GARDEN-MAKING SUGGESTIONS for the Utilising of Home Grounds. By L. H. BAILEY. Globe 8vo, 4s. net.

THE CHEMISTRY OF THE GARDEN.
A PRIMER FOR AMATEURS AND YOUNG GARDENERS.
By **HERBERT H. COUSINS, M.A.**, Oxford Lecturer in Chemistry at the South-Eastern Agricultural College, Wye, Kent. With an INTRODUCTION by **J. WRIGHT, F.R.H.S.** **Pott 8vo, 1s.**

North British Agriculturist.—"A very useful handbook. . . . The author is well up in his subject, and sets forth the scientific and practical facts in a very lucid, succinct, and intelligible style."

A PRIMER OF PRACTICAL HORTICULTURE. Ten Lectures delivered for the Surrey County Council. By J. WRIGHT, F.R.H.S. Pott 8vo, 1s.

The Journal of Horticulture.—"The Primer will be useful for distribution amongst cottagers and allotment-holders, and not less so to young gardeners; also to some who are not very young, as well as to amateurs, while it contains points for dilation by [illegible]."

GARDEN FLOWERS and PLANTS. A Primer for Amateurs. By J. WRIGHT, F.R.H.S. With 50 Illustrations. Pott 8vo, 1s.

Journal of Horticulture.—"A most comprehensive and instructive little book."

VEGETABLE CULTURE. A Primer for Amateurs, Cottagers, and Allotment-holders. By ALEXANDER DEAN, F.R.H.S. Edited by J. WRIGHT. With 38 Illustrations. Pott 8vo, 1s.

Journal of Horticulture.—"'Vegetable Culture' is as thorough, concise, and instructive as either of the preceding Primers, and more than that need not be said."

GREENHOUSE and WINDOW PLANTS. A Primer for Amateurs. By CHARLES COLLINS. Edited by J. WRIGHT, F.R.H.S. With 38 Illustrations. Pott 8vo, 1s.

Nature Notes.—"This little book of 154 pages is crammed with useful information for would-be growers of greenhouse and window plants. We hope Mr. Collins' little book will secure as large an amount of patronage as it certainly deserves."

THE BOOK OF THE ROSE. By the Rev. A. FOSTER-MELLIAR, M.A., Rector of Sproughton, Suffolk. Illustrated. Extra crown 8vo, 8s. 6d. net.

Gardeners' Chronicle.—"You are told exactly what to do; and you must be exacting indeed if you find any point on which you desire information that is not included in these fourteen chapters. . . . This charming and instructive volume."

FARM and GARDEN INSECTS. By WILLIAM SOMERVILLE, D.Œc.(Mon.), D.Sc.(Dun.), B.Sc.(Edin.), F.R.S E., F.L.S. With 46 Illustrations. Pott 8vo, 1s.

Nature Notes.—"This is the cheapest little manual of injurious insects which we have seen."

THE SOIL: its Nature, Relations, and Fundamental Principles of Management. By Professor F. H. KING. Fcap. 8vo, 3s. net.

THE DAHLIA: its History and Cultivation. By RICHARD DEAN, F.R.H.S., ROBERT FIFE, F.R.H.S., JOHN BALLANTYNE, STEPHEN JONES, and WILLIAM CUTHBERTSON, F.R.H.S. Illustrated. Cr. 8vo. Price 1s. 6d. (Paper, 1s.)

Gardening World.—"To Dahlia lovers and would-be cultivators the book is well worth the money."

PASTURES and PASTURE PLANTS. By WILLIAM TOOGOOD. Demy 8vo, sewed, 1s. 6d. net.

Farming World.—"The book is one of immense value, can be fully relied on, has been written in an extremely comprehensive manner, and should have a large circulation."

Williams'
SHADING MATERIALS.

THE MOST SUITABLE FOR
SHADING ORCHIDS; FERNS,
Palms, and Stove and
GREENHOUSE PLANTS

WILLIAMS' HOTHOUSE SHADING.

It is a strong, durable Cotton Netting, woven in squares so close as to exclude the direct rays of the sun, but admitting the greatest amount of light attainable through shading.

It withstands the weather better than any other class of Shading, and may be beneficially used on account of the thickness of its texture, during cold weather, to keep the frost out. The leading Orchid and Plant Growers in the country have used this material for some years, and speak very highly of it, pronouncing it to be the very best material for Plants they have ever used.

Blinds made up and fixed complete.

Sold in pieces 30 yards long by 1¼ yards wide
Price **40s.** each. Samples submitted gratis.

WILLIAMS' "EUREKA" SHADING. *Regtd.*

This new shading is in the form of a white powder, and is prepared for use by applying boiling water to the compound, and allowing it to cool, when it can be applied by means of a brush. It dries instantaneously, and can be rubbed off easily when moist. This shading may be used for GREENHOUSES, SKYLIGHTS, WINDOWS, &c.

Sold in 1 lb. packets, with directions for use, price **1s.** each.

1 lb. free by parcel post for 1s. 3d.

2 lb. free by parcel post for 2s. 4d.

Each packet will make half a gallon of shading material when mixed. It is a great improvement on anything hitherto offered, and lasts the whole season.

NOTES OF THE WEEK.

A STARTLING STATEMENT.

A DISTINGUISHED horticulturist gave expression a short time since to the apprehension that many of the large trees about the country, and especially in and near towns, are slowly but surely dying from dryness at the roots. There is too much reason to fear that the statement carries with it a conviction as to its truth which raises it above the level of a mere opinion of an alarmist. Even in the country, away from the impure atmosphere which encompasses crowded districts, there are to be noticed indications that many trees of great dimensions show signs of decay, and that not merely from old age. We have had long spells of drought during the past few years, and their effects have been perceived deeper down in the soil than is generally supposed. A planter informed us a few days ago that two feet below the surface in the cases of various soils, there is much dryness. Trees planted on mounds to secure picturesque effects appear to be suffering severely in many instances. When we come to towns and their suburbs, where sewerage works and elaborate artificial drainage are resorted to, there are indications of decay in trees that induce serious misgivings. We see our streets being planted, but the surfaces above the roots are asphalted over, so that no surface water can reach the roots near the trunk; happy is it if the extremities of their roots can find their way into or near some drains where they come into contact with moisture. There are magnificent trees at Clifton, Bristol; they line the roadway on either side, standing up tall and strong against the everlasting sky; but it is seen many of them occupy the ridge of a slope down which rain water runs to the channels at the sides of the roadway provided to carry off the surface water. What is true at Clifton is unhappily true of many other places; the London parks afford many illustrations of the kind. We plant abundantly; but do we sufficiently recognise the necessity for feeding trees already established, especially such as are of large size, which we have reason to fear are living on too scanty an income? In addition to lack of moisture, there is also to be endured a worn-out soil, which means slow starvation. Trees that had once been in the vigour of development, under whose boughs men and women have walked, and said pleasant things in their praise, are unfortunately on the decline. It is distressing to witness such falling away into something like decrepitude; trees into whose limbs the native strength of the soil had passed, making them the pride and glory of a neighbourhood, visibly declining, and yet, not because they are old; indeed, many are quite in the prime of life. They appeal to us, though not in audible speech; but they seem to say, Give us something to sustain our vigour. Here we are tied hand and foot to some spot, where we have been feeding for many years, until we want food, and, above all, moisture, which is a form of food. If you wish us to salute you with a glorious drapery of green leaves, the deepest, richest green, and start into an even more luxuriant growth, give us the means of doing this—food. Such is the sermon the "tongues in the trees" preach to those who will give heed to their utterances. Corporations and urban district councils take great pride in planting, and in many cases the selection of trees is good, and the work well done; but few of the members appear to be concerned greatly in the after welfare of that they plant. Practical arboriculturists are needed on many of the councils, or some nurserymen with knowledge and needful pertinacity. Let anyone inspect a large tree, such as an elm, which has been bowled over by the irresistible energy of a tremendous gale, and it will be found there is an unimagined dryness of the soil. We would have those in power no longer remain wholly blind and deaf to the fact that trees are as capable in their way of hunger and thirst as the cattle in the homestead. Means of irrigation are ready to hand; if thoughtfulness can be aroused, action may be expected to follow, and to incite to these is the object we have so much at heart.

WHITEWASHING PEACH TREES.

ALTHOUGH whitening the branches of peach trees for the purpose of preventing the absorption of heat and the premature development of the flower buds, is less effective than the shade of boards; it is of considerable value for the purpose, and it has the advantage of being inexpensive. At the Colombia Experimental Station the most suitable preparation for whitening the trees was a wash of lime with one-fifth of skim-milk added to the water, and about one pound of salt dissolved in each pailful. The mixture is applied by means of a spraying machine and the dressing is repeated as frequently as the rains may render necessary, but a wash properly prepared and carefully applied will adhere for some weeks. In Missouri, four applications during the winter and spring months were sufficient to keep the trees whitened sufficiently to effect the object in view, and the first dressing is applied towards the end of December or early in January, and the trees are then sprayed twice to ensure their being thoroughly covered with the whitewash, which is made of a consistency that will just allow it to pass readily through the nozzle of the spraying machine. The buds of the whitewashed trees at Colombia remained dormant until April, while those of trees not treated commenced, under the influence of warm weather, to swell freely at the end of February, and the beginning of March. As in the case of the trees shaded by boards, the buds of those which had received a coating of whitewash suffered but little from the severe weather, but not more than twenty per cent. of the exposed buds passed through the winter uninjured. It is also of interest to state that the whitened buds were about a week later in expanding than the others, and also set their fruit more freely, because this fact appears to show that the whitening of the branches checks the swelling of the buds in winter rather than retarding the development of the flowers in spring, and suggests that no definite opinion on the value of whitewash in retarding the development of the flowers should be expressed until it has been put to a practical test. To demonstrate the influence of colour in heat absorption, thermometers were covered with purple material, and these registered during bright sunny weather an average of fifteen degrees higher than did those covered with white material of precisely the same texture. There is nothing new in this demonstration, for Franklin and Leslie long since proved by experiment the great difference in the absorptive power of black and white material.

THE SCILLY DAFFODIL HARVEST.

THE harvest of daffodils that has been gathered in the Scilly Isles during the past season, has been so unsatisfactory as to fully justify the complaints that are being made on all sides by cultivators of these flowers. Before the close of last year it was seen that the crop would be considerably below that of the previous season; but few of the growers anticipated such unsatisfactory results as have been revealed by the figures now at command. During the first two months of 1897 the consignments of flowers from the islands to the metropolitan and other markets in the United Kingdom, reached a total of three hundred and eleven tons, but in the corresponding months of the current year, only one hundred and sixty-two tons of flowers have been sent to market, or rather more than half the crop of the preceding year. This immense drop has, of course, made a material difference in the returns of the growers, who are indulging in some amount of speculation as to the cause of the check which the industry has unhappily received. There is some difference of opinion upon this point, but it is less than might have been expected, and there appears to be a disposition among the majority to attribute the failure to unfavourable climatic conditions. There may be some justification for the opinion so generally held as unfavourable weather during the season of growth or the ripening of the bulbs would seriously influence the production of flowers. But it may be that a thorough investigation of the course of procedure followed by cultivators of the daffodils in these favoured isles would reveal some weak points and we are strongly inclined to the opinion that it is desirable cultivators should carefully consider whether their practice will not admit of improvement. We suggest this being done, for the results of our inquiries justify the belief that the chief cause of the falling off in the supply of flowers during the past season was not untoward weather but indifferent culture. It would appear that the growers do not sufficiently appreciate the importance of a well-devised course of procedure in the cultivation of daffodils for the production of flowers for market, and, in consequence, the plants do not attain sufficient vigour to ensure satisfactory results. It appears to us that a more thorough preparation of the soil, a more liberal use of suitable manures, and a frequent change of crop, are urgently needed. The importance of a proper rotation is evidently not fully appreciated in the Scilly Isles, and in consequence the daffodils are in many instances grown for too long a period on the same land, with the result that the soil becomes exhausted, and the plants so weakened as to readily suffer from adverse influences. Therefore it is absolutely necessary that something should be done to improve the system of culture, for unless a material change is made without delay, the crops will steadily decrease, and the industry cease to be a source of profit to the islanders.

Gardeners' Orphan Fund.—Charles E. Keyser, Esq., writing from Aldermaston Court, Reading, under date of April, 1898, says: Having consented to occupy the chair on April 20 at the annual Festival Dinner of the Royal Gardeners' Orphan Fund, I wish to appeal to all lovers of gardens and gardening for a liberal response towards this most deserving charity. The object of the fund is to make allowances or grants of money to aid in the maintenance and education of the orphan children of gardeners. At the present time, sixty-four children participate in the benefits of the fund, by an allowance of 5s. per week until they attain the age of fourteen years; special grants are also made towards apprenticing or otherwise promoting the start in life of any boy or girl who may be eligible for such assistance. The principle on which the charity is conducted, is one which strongly recommends itself to the benevolent: the granting of allowances to children in their homes, thereby assisting the mother to maintain her family, is one of the best that can be adopted. From what I have seen of the management of this charity, I can confidently speak of the excellent work it is doing among a deserving class, and of the economical way in which the work is carried out. There are no expensive buildings or offices to maintain. Beyond the payment of necessary working expenses, which are kept at the lowest limit, all monies received are directly applied to the relief of the orphans. I strongly recommend this charity to your benevolent consideration, and trust that you will use your great influence in its support. We trust that Mr. Keyser's appeal on behalf of this excellent charity will meet with a liberal response.

Societies Affiliated with the R.H.S. having expressed a wish that they may be allowed to use the parent society's badge, the Council, desiring to meet this very legitimate wish for some outward symbol of affiliation, but considering it better that the badge should not be actually identical with that in ordinary use by the parent society, have caused a new badge to be struck, which may be used by affiliated societies, on letter paper, schedules, &c., as they may think fit. A printing block of this badge will be presented to every affiliated society (there are now over one hundred) on application to the secretary, and on signing an undertaking to return the same if the affiliation should for any reason be ended.

Horticulture at Manchester.—We are pleased to have evidence of renewed activity in horticultural circles at Manchester, more especially in the work of the Royal Botanical and Horticultural Society of Manchester, which has exercised an important influence for good upon horticultural progress in the United Kingdom during the past half century. Mr. P. Weathers, the curator and secretary of this society, sends us particulars of the arrangements for the current year, and from these we learn that a great horticultural exhibition is to be held from May 27 to June 2; a rose show on July 9; an exhibition of the produce of the gardens of amateurs and cottagers, September 3; and an exhibition of chrysanthemums, November 15 and 16. The first three exhibitions are to be held at Old Trafford, and the chrysanthemum show at the Town Hall. At the Whitsun exhibition orchids receive liberal encouragement, five classes being provided for collections, and the prizes are such as to justify the anticipation of a brisk competition. The prizes in the amateurs' class for a miscellaneous collection are of the value of £20, £12, and £8 respectively, and prizes of the same value are offered for groups of miscellaneous plants arranged for effect on an area not exceeding two hundred square feet; British and exotic ferns, stove and greenhouse plants in bloom, and remarkable for the beauty of their foliage, and hardy herbaceous plants, with a host of other subjects proper to the season have ample provisions made for them. The schedules of the rose and chrysanthemum shows are comprehensive, and that of the cottagers' show is of much interest.

Liquid Air is not, perhaps, of such immediate importance to the gardener as the mixture of oxygen, nitrogen, and carbonic acid, which constitutes atmospheric air under normal conditions, but the process of liquefaction is so highly interesting as to justify some reference to it. Dr. Linde has invented an ingenious air-liquefying machine, and this has recently been on exhibition at the rooms of the Society of Arts. It is based on the fact that air, not being a "perfect gas," undergoes a reduction of temperature when it is suddenly allowed to expand from a high to a low pressure. This cooling effect is made cumulative by allowing each lot of cooled air in turn to abstract heat from the air in the chamber previous to expansion, so that the expanded air continually starts from a lower temperature. In this way a temperature is obtained low enough to produce liquefaction, and allow even of liquid air being drawn off by a tap—of course, under proper conditions to prevent heat getting to it. The machine on exhibition gives off nine-tenths of a litre of liquid air an hour, with a continuous expenditure of three horse power. The reduction of pressure undergone by the air is from two hundred to sixteen atmospheres. The liquefaction of the nitrogen and oxygen in the air is simultaneous, but the nitrogen evaporates first, so that in this way pure liquid oxygen can be obtained.

Pollen Grains.—With what marvellous beauty Nature fashions even the smallest of her productions was strikingly illustrated at the meeting of the Royal Botanic Society on the 19th ult., under the chairmanship of Dr. St. George Mivart, F.R.S., when the Fellows gave an exhibition of pollen grains as seen under the miscroscope. Many of the slides were of a most interesting nature, and the development of the pollen was shown by a series ranging from its first inception within the anther of the flower up to the formation of the pollen tube and the fertilisation of the ovule. Other slides were much admired for the great beauty of the markings upon the wall of the grains.

Chionodoxas continue to enjoy a high degree of popularity, and deservedly so, for they are so exquisitely beautiful that in the season of flowering they have no superiors. In the Royal Gardens, Kew, they are grown in immense numbers, and at the present time they constitute a delightful feature. C. Luciliæ forms a series of beautiful pictures on the slopes and ledges of the rock garden, and this species and C. sardensis is used with much success in carpeting the surface of shrubbery borders in the same way as the snowdrops in the example of which we gave an illustration in our issue of the 19th inst.

Hyacinth Culture for Exhibition has of late years so materially declined in the neighbourhood of the metropolis that it is now a rare occurrence for these flowers to be contributed in any considerable quantities and in exhibition form at the metropolitan meetings. Hence the collection of splendidly grown specimens exhibited by Messrs. W. Paul and Son at the meeting of the Royal Botanic Society on Wednesday was of much interest, more particularly to those who remember the time when a hyacinth show formed one of the most important items in the society's programme. The specimens staged were equally remarkable for their short, stout foliage and massive spikes, and reminded us of the examples which had on more than one occasion placed the firm at the head of prize winners in a severe competition.

Early Herbals and Old Gardening Books are steadily acquiring importance, and the remarkable collection included in the important sale of books by Messrs. Sotheby, Wilkinson, and Hodge during the week ending the 26th ult. created an immense amount of interest among book lovers. The early herbals included a French MS. of some three hundred and fourteen pages, entitled "Le Livre des Simples Médécines," written in the fifteenth century. This important manuscript contains besides the herbal several treatises on diseases and their remedies, written partly on vellum and partly on paper, and is embellished by several hundred coloured drawings of plants, &c., and ten paintings of hunting scenes and husbandry processes. The biddings were brisk, and soon reached £99, when the hammer fell, Mr. Quaritch being the purchaser. Not less spirited was the competition for "Arbolayre cotenãt la Qualitey et virtus Proprietez des Herbs," a small folio, printed at Lyons by Husz, probably in 1485, and so exceedingly rare that only one other copy is known to exist, and that is in the Bibliothèque National at Paris. It is a translation of the German Herbal printed at Bale, and contains numerous fine woodcuts, that at the back of the title being particularly good. This was sold to Mr. Robson for £68. Several copies of the "Buch der Natur," one of the finest of the woodcut books produced at Augsburg in the fifteenth century, were offered, and they realised good prices. The extremely rare first edition, printed at Augsburg by Bamler in 1475, is a small folio, illustrated by numerous full-page woodcuts, coloured by a contemporary artist, practically uncut, and in the original publisher's binding, and after a spirited bidding the hammer fell at £101, the purchaser being Mr. Quaritch. The rare first edition of "Herbarius sive Aggregator," a small quarto of one hundred and seventy-four leaves, illustrated by one hundred and fifty woodcuts of plants in contemporary colouring, and issued from Schoeffer's press, sold for £25. There were three editions of "Hortus Sanitatus Herbis et Plantis," a small folio, illustrated with spirited woodcuts of plants and gardening operations; the copy printed by Pryss in 1487 realised £14; that issued from the press of R. Beck in 1490 £15 15s., or five shillings more than was obtained for Lord Ashburnham's copy sold in December last; and the extremely rare *editio princeps*, with a date, printed by J. Meydenbach in 1491, £35 10s. The old gardening books included a fine copy on thick paper of "Buillard's Flora Parisiensis," published in 1776, and containing six hundred and forty finely coloured plates (£10 10s.); "Bussatos Giardino di Agricoltura," a rare work, printed at Venice in 1599, and containing illustrations of gardening utensils, grafting, &c. (£2 9s.); "Chambers's Plans and Views of Kew Gardens," a folio containing fine engravings of the gardens, published in 1763 (£2 2s.); "The Countryman's Recreation," a fine copy of one of the rarest of the old English books on gardening, and published in 1653 (£8 5s.); "Dunstall's Book of Flowers, Fruits, Beasts, Flys, and Worms," four vols., fully illustrated, published in the years 1661-63, an interesting book (£15); "Desgot's Parterres," a folio with illustrations of flower gardens, by Le [illegible] and others, published in 1730 (£3); "Ferrari's Florum Cultura," a rare work with engravings of flowers and gardens, and published at Rome, 1633 (£3); "Flowers," a collection of thirty-two drawings, in water-colours, of flowers, supposed to be by Marie Joseph de Saxe, mother of Louis XVI. (£6); "Flower Garden Displayed," an interesting and rare work published in 1732, and containing some four hundred representations of the most beautiful flowers of the period (£[illegible] 15s.); "Franeau's Jardin D'Hyver," a rare quarto, published in 1616, and embellished with numerous plates (£5 2s. 6d.); "Lawson's A New Orchard and Garden," an interesting work containing directions for planting orchards, grafting fruit trees as practised in the seventeenth century; "Tulips," a fine folio published Paris in 1781, and containing forty finely-executed coloured plates of the finest florists' tulips then in cultivation; "Ehret's Plantæ Selectæ," a rare [illegible] containing one hundred superbly coloured plates and mezzotint portraits of [illegible] Dionysius, D. Christophorus, Jacobus Trew, and Joannes Jacobus Haid; "Elsholtz Garten Baw," a somewhat interesting German book, published [illegible] Berlin towards the close of the seventeenth century. There were many other old German books of special interest, but space will not permit mention being made of them, except to say that a good copy of the "Catalogue of Plants" propagated for sale by a Society of Gardeners in London in 1730, and embellished with a fine frontispiece and twenty-one coloured plates, realised £2 2s.

At the British Association Meeting to be held at Bristol the [illegible] of Section K, Botany, will be Professor F. O. Bower, F.R.S., president; Professor Marshall Ward, F.R.S., vice-president; Mr. A. C. Seward, Professor J. B. Farmer, and Mr. J. W. White, secretaries, the former to act as recorder to the section.

Flowers for the London Schools.—An appeal is once again being made on behalf of the children in the London elementary schools for a small supply of either wild or cultivated flowers weekly or fortnightly throughout the spring, summer, and autumn. There is a fund known as the Children's Flower Fund, which defrays all expenses, so that friends in the country are only asked to collect and forward the blooms. If those who are continually amid flowers, foliage, and pure air could but understand the pleasure a few flowers in a school affords the children and teachers, there would be no lack of helpers. The flowers not only brighten the school and give pleasure, but they are useful for object lessons, for drawing, and also in the numerous botanical classes now held. Full particulars can be obtained from Miss M. S. Beard, 36, Ridgmount Gardens, W.C. Last year two hundred and seventy-four boxes of flowers were sent, and these supplied twenty-nine schools, leaving nearly nine hundred and fifty public elementary schools flowerless.

Malformed Scotch Fir.—Mr. H. J. Veitch submitted to the Scientific Committee a curious mass of stunted boughs, the whole resembling a hedgehog, and probably caused originally by a phytoptus fungus. Dr. Masters observed that short boughs struck from such specimens were used as miniature trees, for rockwork, &c.

Fruit Sellers and Buyers are at present each airing their grievances. We have shown how the buyers, or middlemen, have combined with a view to obtaining redress when the goods bought do not come up to their expectations. The brokers retort that while losses do occur, yet quite as frequently the buyer obtains better packages than he expects, but makes no return of the difference in value. One of the brokers' conditions of sale is that "Intending buyers are requested to thoroughly inspect the bulks, as the goods will be delivered from the warehouses with all faults and defects, and no allowance will be made for errors of description or defects of quality, quantity, or condition. If any of the contents of any package are spoilt, damaged, unsound, or otherwise defective, so as to be unfit for human consumption, such defective goods are not intended by the brokers or purchased by the buyers for the food of man; and the buyers shall separate such defective goods from the bulk, and shall not use or sell any such defective goods for the food of man." The brokers hit the buyers rather hard when they refer to the current prices of lemons; these are now selling at from 3s. to 6s. per case of three hundred to three hundred and fifty fruits, and yet the consumer cannot obtain good lemons for less than one-half penny or one penny each, mostly the latter figure.

The Crystal Palace has throughout its existence been so closely connected with horticulture, especially by reason of the fine exhibitions provided there, that our readers cannot fail to be interested in the movement now on foot for its purchase by and for the nation. At a recent conference of local authorities, presided over by the Lord Mayor, a resolution was moved, "That in the opinion of this conference the present is an opportune time for the Government to secure as a permanent place of instruction and recreation the Crystal Palace and its grounds as a national institution; and, further, that this conference is of opinion that every means should be taken to prevail on the Government to acquire and maintain the same for the enjoyment of the people for ever." The Crystal Palace can be acquired for £750,000, and it is urged that part of this sum should be defrayed from the large amount in the hands of the Royal Commissioners of the International Exhibition of 1851. We understand that leave to deposit a petition for a Bill has been asked of the House of Commons on behalf of the Crystal Palace Company. The petition shows that the financial position of the Crystal Palace is such that there is risk of a collapse of the undertaking. No interest has been paid for some years on the second (1887) debenture stock, and unless the concern is at once reorganized, and fresh working capital is introduced, the revenue may shortly become insufficient to meet the interest on the first debenture stock. Certain proposals have recently been made to the directors as to a plan of reconstruction, under which additional capital may be provided, and a provisional agreement for carrying out this plan is in course of completion. The amount of the company's capital and debenture stock is, however, admittedly much beyond the present value of the property. The plan now in contemplation involves a very large reduction of the nominal capital, and the conversion into an amount more nearly representing the value of the property—a complete reorganization of the capital being essential before any further capital can be raised. The necessary reorganization can only be effected by an Act of Parliament. The petitioners humbly submit that the preservation of the Crystal Palace, and of the educational and other institutions carried on by the company in connection therewith, is a matter of public importance. The area of the site of the palace and grounds is about 190 acres of freehold land. The petitioners apprehend that unless they obtain leave to introduce their Bill in the present Session, the chance which they now have of obtaining the required additional capital will be lost. The petition bears the seal of the company, and is signed on its behalf by the chairman and secretary. Jurisdiction in the matter of the petition is with the Standing Order Committee of both Houses.

The Scilly Isles Flower Trade for January and February of the present years shows a large falling off from the corresponding period of 1897. In 1897 the export of cut flowers for the two first months of the year totalled to three hundred and eleven tons, but this season it fell to one hundred and sixty-two tons. This is due to the failure of early crops, but higher prices than usual have almost equalised matters.

Twin Apple.—A remarkable monstrosity was sent to R.H.S. Scientific Committee. Instead of being the result of the fusion of two flowers, as occurs in tomatoes—*i.e.*, a "synanthic" condition, a vertical section revealed the fact that they were the result of a bifurcation of the axis below, the under side of the apple giving no signs of its being a twin.

LEAVES FROM A RAMBLER'S NOTE-BOOK.

BEATEN BY A HIDDEN FOE.

"THERE never were finer black currants went out of Sheppey than were grown in this plantation, though I say it as shouldn't; and now look at them. It's enough to break a man's heart, it really is, to have the most paying crop we had clean ruined in about three seasons." The speaker was a fruit grower who, by dint of hard work and perseverance, has turned a rough piece of freehold ground into a pleasant homestead, and does his best to turn it to profit by the cultivation of fruit. The situation is a hillside gently rising from the lowlands of the Isle of Sheppey, and within sound of the hammers at Sheerness Dockyard. Though somewhat bleak and wind-swept, the monotony of the landscape is counterbalanced by the fertility of the soil, which, like all that district of Kent, is well adapted for fruit culture. We stood by the side of a huge pile of black currant bushes which had been grubbed, and after bringing grist to the mill in a substantial quantity for some years, were placed there to fill their last office—fuel for the fire.

Every swollen bud on the bushes told its own tale of woe, and the disconsolate air of the grower as he gazed on the remains of his once profitable crop seemed to suggest that he was helpless, and, confessing himself beaten, had thrown up the sponge. There has been some controversy in these pages recently respecting the ravages of the black currant bud mite, with suggestions for its extermination; but while the grass is growing the horse is starving, and it is when one is brought face to face with such an instance as this that one realizes fully the terrible devastation caused by this invisible pest. There are many growers who know nothing of it, fortunately for them, and, indeed, are unaware of its existence; but this is no proof against its spreading, and, in the interests of the black currant industry, no efforts should be spared ere we become, so far as is possible, conversant with the life history of the pest, and the means of combating it. With apologies for digression, I return to the grower and his troubles. "It's not so bad fighting an enemy when you can see him," was his logical assertion, "but with this thing we're completely in the dark. We know nothing about it, and, what is more, no one is able to tell us much. It's there, that's evident"—pointing to the heap before him—"but where it came from, what it is, and how it spreads is quite beyond me. I suppose the creature is alive in the bud, but what beats me is how it gets there. There seems nothing but losses nowadays, and it was the best crop we had. It's some new-fangled thing, I suppose, come to make bad times worse, for I have been growing currants all my life, and never heard of it before."

"When did it first appear?" I asked. "About three seasons ago, as near as I can remember, I noticed some of the buds swelling early as I thought. I showed them to a friend of mine, and he said I was going to have a good crop as the buds were coming on so well; but as for mite, I never dreamt of such a thing, because I'd never heard of it. Well, I didn't take much notice of it that season, as I thought it was owing to the mild spring, but the next year they were worse. One day a man who had been in Scotland called on me, and in talking about black currants, he said they could do no good with them there on account of the 'button bud.' Button bud, said I, what's that? Why, you've got it, says he, picking off a shoot, and since then I've had good reason to know what it is, and so has many another in these parts." "What did you do then?" I asked. "Well, I began to make inquiries, and I found out what the swelling of the buds meant. I think sometimes that if I had known soon enough what it was I might have checked it that first season, but you see I'd never heard of it. Somebody told me to pick the swollen buds off and use lime, which I did, but they got worse, and then I thought if I cut the bushes down entirely the fresh shoots would be alright." "Did it answer?" "Come and look," was the reply, and leading the way up the plantation we came across a row of bushes that had been cut back to the ground with the hope of clearing the pest, but with no effect, as almost every bud bore unmistakeable evidence that it was harbouring a mite. "It's no good," he said, "they'll have to come out, though it's a pity, for black currants do so well on this land. When we cut away all the old wood and let them make a fresh start I thought they must grow free, but it is, as I said before, the thing's a mystery."

"You form no idea of the cause, I suppose?" "None," was the emphatic reply. "I was told once that perhaps I had over manured the ground, and I thought there might be something in it, as I feed the bushes well, but that theory is no good, because a neighbour of mine is just in the same plight, and he has never manured at all. The decision I've come to is that it has been brought into the neighbourhood through planting from infested stocks, though in some plantations quite close to here the bushes are quite free, and in others they are just as bad, though no fresh planting has taken place for years. I have heard that there is a variety of black currant which is quite free from it, but I don't know; the proof of the pudding is in the eating." "What shall you do to replace the loss?" I asked. "I'm afraid I can't replace it," said the grower. "My black currants have sold at the rate of a hundred pounds an acre more than once, and I thought of growing nothing else. I'm glad I didn't though, as this has taught me that its always wise not to have all your eggs in one basket. I've planted up much of the ground with gooseberries, but I shall have another try at the black currants if I can get a fresh stock entirely, and feel sure that they are free from mite; but there's the difficulty—knowing." "But havn't you read about this pest?" "Oh yes, but I never got much satisfaction out of that. I've seen pictures of it, showing its jaws and body, how many legs it has, and all the rest of it, but what is the good of that? Then we hear that this might prevent it, and perhaps the other would kill it; but to me there seems only one remedy, and that is fire, though I do regret that I did not know what it was at first."

Such are the sentiments of a market grower, who has good reason for being acquainted with the black currant bud mite, for in a few years he has lost the principal source of income. This is not a solitary instance, and the question at issue is whether, if something is not done to deal effectually with this enemy, the cultivation of the black currant in England will not become an industry of the past. In Kent the fruit is largely grown, but when the advent of the mite means the ruin of a plantation in so short a time, a general spread of it would make the extermination of the fruit by no means impossible. Perhaps the strongest hope lies in the introduction of a variety that is proof against it, though in such an acquisition quality has also to be considered. It is only reasonable to suppose that propagation from infested stocks is a great incentive to the growth of the pest, but there appears to be so little known of the life history of the mite, that it is difficult to say definitely how it spreads. One thing, however, is certain, that among the many enemies of the fruit grower this is one of the most deadly, and at the same time the most mysterious. It is a question that calls for the efforts of scientists and others, and should not be looked at in the light of learning the ways and habits of an interesting, though invisible, insect, but more from the fruit grower's point of view, to whom it is a desperate enemy, and one that seems to become more forcible year by year. It is when among growers who are dependent on black currants to pay their rent that one sees the trouble caused by this unseen foe, and the urgent necessity of means to check the evil. As yet it does not appear to have generally reached an advanced stage, though judging from our scanty knowledge of the pest, and the uncertain means of combating it, we must face the fact that we are in danger of being beaten by an invisible foe. H.

PEACHES IN THE OPEN.

IT is always a pleasing stimulant to read "Lux's" "Morning Mixture." Perhaps all the more so because we cannot always agree with him. The concluding paragraph of his last mixture is keenly satirical, but it is too obvious that some of his latest utterances on potato culture maintain dead silence on greening and ending up of seed potatos as among the surest modes of preventing disease, and of hastening maturity, improving the sample and adding to the weight and bulk of the produce.

I am in no fighting mood, though I cannot agree with him that the high level of out-of-door peach culture in the olden time, of which I have heard and seen a good deal, was, or is, very much of a myth. No, friend "Lux," it was solemn fact, to be reckoned with and learned from if we are to come up to the level of our fathers. Copings, prunings, fly nettings, &c., may have exerted a powerful influence on the out-of-door culture of peaches in British gardens, but the strong statement that peaches are indubitably more tender than apples, pears, or plums I cannot endorse. Where the crops of the last three have been ruined peaches have again and again escaped. "Lux" will no doubt say, Yes, but your peaches were on walls, and the other fruits in the open. Yes and No, is my answer. Of course, none of us have succeeded, unless in very exceptional sites, soils, and seasons, in ripening peaches or nectarines of high quality in the open air. But, on the other hand, who amongst us have not lost crops of plums and pears on the same walls on which peaches have ripened in safety? I think, however, it would be safe to assume when "Lux" writes of the hardiness or tenderness of these he means under their ordinary conditions or environments of culture; that is, the peaches on walls and the apples, pears and plums in the open. And if so, I can give an emphatic No to his assertion that the peach is indubitably the more tender.

Then "Lux" has another strong string to his bow. Look, he exclaims, over large nursery quarters after a severe frost, and the true lesson of the general non-success of peaches out of doors will be learned at a glance. Well, I have often looked, and have failed to learn the same lesson of the tenderness of peaches as "Lux." Allow me to say what I have learned: The crying evils of gross stocks, rich soils, heavy manuring; the concentration of the vigour of the maiden peaches into shoots long and strong as fishing-rods, making them delicious tender food for the first hungry taste of Jack Frost, and model homes for canker, mildew, and all the diseases that peaches are heir to in our fitful climate. But I have also seen thousands of young peach trees, under less stimulating cultural environments, with wood and buds of moderate size, hard and brown almost as nuts, and so thoroughly ripe and dormant as to pass through our normal frosts in the open with impunity; though, of course, after October or November planting, the safety of such trees is made doubly secure by affording them the shelter of a wall.

The decline and fall of our modern culture of peaches in the open-air in Britain—if it has declined and fallen, which I am not at present careful to prove—has come about, not from the cooling down of our climate, but for lack of the due preparation of our young trees, and more careful culture and training of the old ones. "Lux" will hardly deny that our fathers spent far more time on the nurture and training of their peaches and other wall trees than we do to-day. Glass has long been the rage and fashion in horticulture, and grapes and other fruits under glass, orchids, chrysanthemums, fine foliage plants, &c., absorb much of the time, the skill, and the patience that used to be devoted to peaches in the open. Even "Lux" himself seems to have something of this spirit when he penned the sentence about copings, prunings, greenfly, &c.; yet I am sure he would be the last to deny that one cannot grow perfect peach trees or fruits and greenfly together. Our fathers fought the latter to the death with the garden syringe or engine, and if modern growers had the time and the patience to go and do likewise it would be found that their success was no myth, but sober, every-day fact. The cry of most peaches in the open to-day is not for a warmer climate, but more water at top or bottom. D. T. FISH.

OUTDOOR TOMATO CULTURE.

NOW that tomato cultivation has become so popular, information is eagerly sought after, especially by amateurs, and as I have recently had several letters, many from readers of the GARDENERS' MAGAZINE, asking for information, I may be allowed to make a few remarks concerning the cultivation of this vegetable. It is just possible for all amateurs to grow their own tomatos, provided they have a small garden that receives a little sunshine; but very much depends upon the energy and care of the cultivator. If one has glass, they had much better purchase a few strong plants towards the end of May, but by means of a greenhouse or frame they may be raised very easily. For outdoor culture tomatos must never at any time be coddled, but from the first be brought up hardily. For outdoor crops two sowings ought always to be made to provide a succession, because the earlier varieties will in a long season become exhausted; whereas in a later sowing there will be a lot ripening upon the plants which will keep the supply going well nigh on to Christmas, and this is a distinct advantage. I have known a cottager to keep tomatos up to Christmas.

Seeds should be sown in a pot or small box, but either should be well drained, that is, put plenty of broken potsherds at the bottom of the pot or box. If a few plants only are required, I should strongly advise the use of five-inch pots, there not being so much anxiety about damping off with such. The first batch should be sown from about the third week in February to the second week in March, the time entirely depending upon the means at hand to subsequently grow them on. If these are in a frame previously placed upon a bed of leaves, or other fermenting material, the seedlings will begin to show in a temperature of fifty-five degrees, in about eight to ten days; and as soon as they are well up admit a little air for an hour or two each day, but this must be given at the back or top of the light, and the light should be tilted up with a piece of wood or a small stone; about half an inch will be ample, unless the sun shines very hot, when more would be necessary at the middle of the day. While upon this subject, I would lay stress upon airing at the top, instead of the bottom, for by opening at the highest point, the moisture escapes at once, and after this, fresh air comes in gently or gradually, and takes the place of the moist close atmosphere. All airing should be done upon similar lines.

Soil used for seedlings need not be very rich, but a good mixture for potting should consist of fresh turfy loam with a very small quantity of leaf soil and spent hot-bed or mushroom manure, the whole to be used rough; a few handfuls of bone-meal may be mixed with the soil, for the last potting, with considerable advantage. When the seedlings are about three inches in height, they should be pricked out singly into small pots, and great care should here be exercised that the stem be not squeezed or injured, as this may cause a check, if not absolutely kill the tender plant; after the operation of potting off is finished, put the plants back into the frame, or on a shelf in the house where they may be kept close for a day or two to enable them to establish themselves in the new soil, after which they may be aired again daily, and above all kept near the glass, in order to keep them dwarf and stocky. When the pots are full of roots, another shift into larger pots should be made, and still another, the soil being about the same as before, but made very firm. Gradually give more air and finally expose altogether under a wall, or other suitable protection, but they should be covered up at night with some light protecting material, and even after they are planted out they should be protected in case of frost.

When ready for planting dig out a hole and put therein a little fresh soil, such as collected road scrapings, this furnishing excellent material for tomatos. The plants may be placed in the open ground if no wall space be at command, and trained up sticks or hurdles, or, in fact, anything to keep them from touching the ground. As they make growth carefully watch them, and tie with strong raffia as often as is necessary so to do. Never neglect this duty at the proper time, or breakages will occur, and all the care and work of perhaps a couple of months will be undone. As the plants make headway carefully pinch out all the side shoots or laterals. This is necessary to keep the main stem strong, and one stem, as a general rule, will yield a good supply of excellent fruit; but if it is desirable to have several stems the point should be pinched out quite early, so that all the stems intended to be grown may be of equal strength. If extra fine fruit are desired the clusters should be thinned directly it is seen how many fruits have set. During the growing season the plants should never suffer from drought, but should be fed now and again with farmyard liquid or other manures obtainable.

Other uses may be made of spare tomato plants. They may be grown in pots and trained over arches or porches of dwelling-houses, and when such positions are due south I have seen excellent crops taken, or they may be trained in a variety of fancy ways, as they can be directed to travel at the will of the grower. All those fruits that do not ripen during September should be taken inside, when they may be hung up in a warm place where it is not damp. Examine them frequently, and cut them if it is necessary. The best variety I have grown out of doors is Carter's Outdoor, a free grower that produces fruits very early and of good shape, colour and flavour. Another very well-known variety is the Sutton's Earliest of All. The best late variety I have grown is Ham Green, but I should strongly advise all who intend to grow outdoor tomatos largely to make early and late sowings of the first-mentioned sorts.

W. A. COOK.

Compton Basset.

THE BEST GUIDE to the garden for the whole year is the "Gardening Year Book," [illegible] containing practical articles on the cultivation of Flowers, Fruit, Vegetables, &c. "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

FORCED LILAC.

THROUGHOUT the north of Germany and also in many parts of France lilacs are cultivated extensively for forcing, and subsequently the business of forcing is also largely entered into, for on the Continent, as at home, lilac—especially white lilac—is in great demand during the winter. Whether our moist insular climate is altogether to be blamed with regard to our non-production of lilac bushes fit for forcing, is rather an open question, but it is a fact that hitherto the lilacs forced in the British Isles are chiefly imported from France and Germany. It is probable that in the sunniest parts of our country suitable plants might be cultivated to, in some degree, meet the demand. A somewhat poor l is necessary, frequent transplantings to ensure a quantity of short fibrous roots, plenty of moisture during growth and a position that would ensure a thorough ripening of the wood. We are persuaded it would also be a great gain to grow the plants in pots one whole season before forcing, plunging the pots during that season, and otherwise caring for the plants. Among the most pleasing sights to be seen in the Hamburg and Berlin nurseries during the earliest months of the year, are the houses of forced lilacs, for not only do our continental neighbours grow plants for others to force, but they produce flowers of the highest quality and in quantity for home consumption, and in a smaller degree for export. Those who visited the opening display of the recent Hamburg Horticultural Exhibition, will remember how beautiful were the huge groups of lilacs in wonderful variety and deliciously fragrant that adorned the big hall and a minor hall on the other side of the grounds. Many of the varieties not yet thoroughly well known in this country force as readily as the older forms. In the matter of improving lilacs, fixing and distributing new varieties, the French florists have led the way, and deserve our thanks for the many splendid single and double forms now in commerce.

HOUSE OF FORCED LILACS AT BERLIN.

The accompanying illustration represents part of a lilac house in the nursery of Mr. Gustav S. Schultz, Lichtenberg, Berlin, and the photograph from which it was reproduced was taken a few days before Christmas. Mr. Schultz finds it profitable to produce large supplies of flowers during December, January, and February, as during those months the demand is keen and prices high. The varieties represented are Charles X., a deep purplish form that comes white when forced in the dark, and is one of the best for the work; and Marie Legraye, a handsome and large-flowered single white form. Other sorts that find favour in Germany, are the red Souvenir de Leon Spathe; the pale lilac, double-flowered Michael Buchner; the superb double white Madame Lemoine, and the pure white Alba grandiflora.

The Hop Hornbeam.—Referring to your note in a recent issue of the GARDENERS' MAGAZINE respecting the hop hornbeam tree, I beg to say that my father tells me that there is a fine healthy tree in the grounds of Batts Park, Taunton, the only tree of the kind he ever saw, except the one at Kew.—H. CLARKE, *Taunton.*

THE BENDING-STALKED MARIGOLDS.

THE genus of South African composites known as Dimorphotheca is closely allied to the better known Calendula. It contains twenty or so species, and these, by reason of the slender and slightly bent stems supporting the flower heads, were formerly known as bending-stalked marigolds, an appropriate, but not euphonious title. The species are either annual herbs or perennial and shrubby; the leaves are usually narrow, entire, and more or less toothed or cut. The flower heads vary in colour from white to scarlet, and when well developed are about three inches across. So far as cultivation is concerned they are very easily managed; being half hardy they may be used for the flower garden during the summer and for greenhouse decoration during the winter. The perennial species are readily propagated from cuttings if given a little extra warmth until rooted. For the annuals it is only necessary to sow seeds in heat during February and March, gradually hardening off the seedlings, so that they are ready for planting out in May. None of the species like over much moisture, so that when grown in pots they should have ample drainage afforded and be placed in a sandy compost that is otherwise fairly rich.

The white flowered Dimorphothecas are:—D. annua, from Simon's Bay, introduced as far back as 1752. D. Tragus, a large-flowered species with purple or bronze shading along the underside of the ray florets; during the summer the flower heads commence to expand about seven a.m., and are fully open soon after mid-day, but by three o'clock they begin to fold up again. D. graminifolia has grassy foliage and big heads consisting of purplish disk florets, and rays that are white above and brownish orange below. D. pluvialis, D. hybrida, D. medicaulis, and D. fruticosa all have white ray florets with either purple or yellow along the lower side, or in the disk florets. A newer introduction is D. Ecklonis that seems fairly plentiful in the neighbourhood of Port Elizabeth. Collected specimens are much more dwarf than those cultivated in this country, the latter attaining a height of eighteen inches at flowering time in the month of July. Whether this will become popular it is difficult to say, but it is easily grown from imported seed and has been flowered as a bedding plan at Kew. The species is shrubby at the base and clothed with oblanceolate, subsessile leaves sparingly toothed, and pale green. The flower heads measure three inches across and, as seen in the illustration, contain about sixteen white ray florets each, these being striped and shaded with violet—save for a white margin —on the lower surface; the small disk florets are also of a blue shade.

Species with brighter flower heads are fairly numerous, and some of them are so attractive that they seem to invite improvement by means of selection of seedlings. D. aurantiaca, referred to by Aiton, and figured in the *Bot. Mag.* t. 408, or just a hundred years ago, produces bright orange coloured ray florets as its name implies. D. chrysanthemifolia introduced about 1790 is an early flowering species with bright yellow rays and dark disk florets; D. dentata introduced about the same time, is also yellow. D. cuneata, better known, perhaps as Arctotes glutinosa, is remarkable for its clammy or sticky leaves and stems; it is also a very bright plant the ray florets being of the deepest orange or orange-scarlet shade. D. Barbariæ, introduced from Caffraria in 1862, has purplish flower heads, and is synonymous with D. lilacina; it is perennial, and well repays attention as a greenhouse plant. K. P.

Potatos for Exhibition.—I always read with the greatest possible pleasure the Morning Mixture prepared for us by "Lux." It is easy to take, and generally has a beneficial effect. I must thank him for the honour he does me in reading my articles, and if, under the above heading, I may seem to be a little in fault, it is because I have endeavoured to deal with the production of high-class vegetables for all purposes, and because "Lux" had surely not read the second part of my article (divided by the editor) when he wrote. I do not for one moment suppose that every reader of the GARDENERS' MAGAZINE is in a position to put in force all my suggestions, but I never mention any but what I know to be possible from practical experience, and which are being carried out in our practice here at the present time. I advise "Peter" to worry his master for a few suitable pots and a good heated pit; and these gained, he will then, I am certain, be able to give good returns for the small outlay. I am looking forward with much interest to the discussion likely to follow anent the production of heavy crops, how they are produced, and who really is the champion.—EDWIN BECKETT.

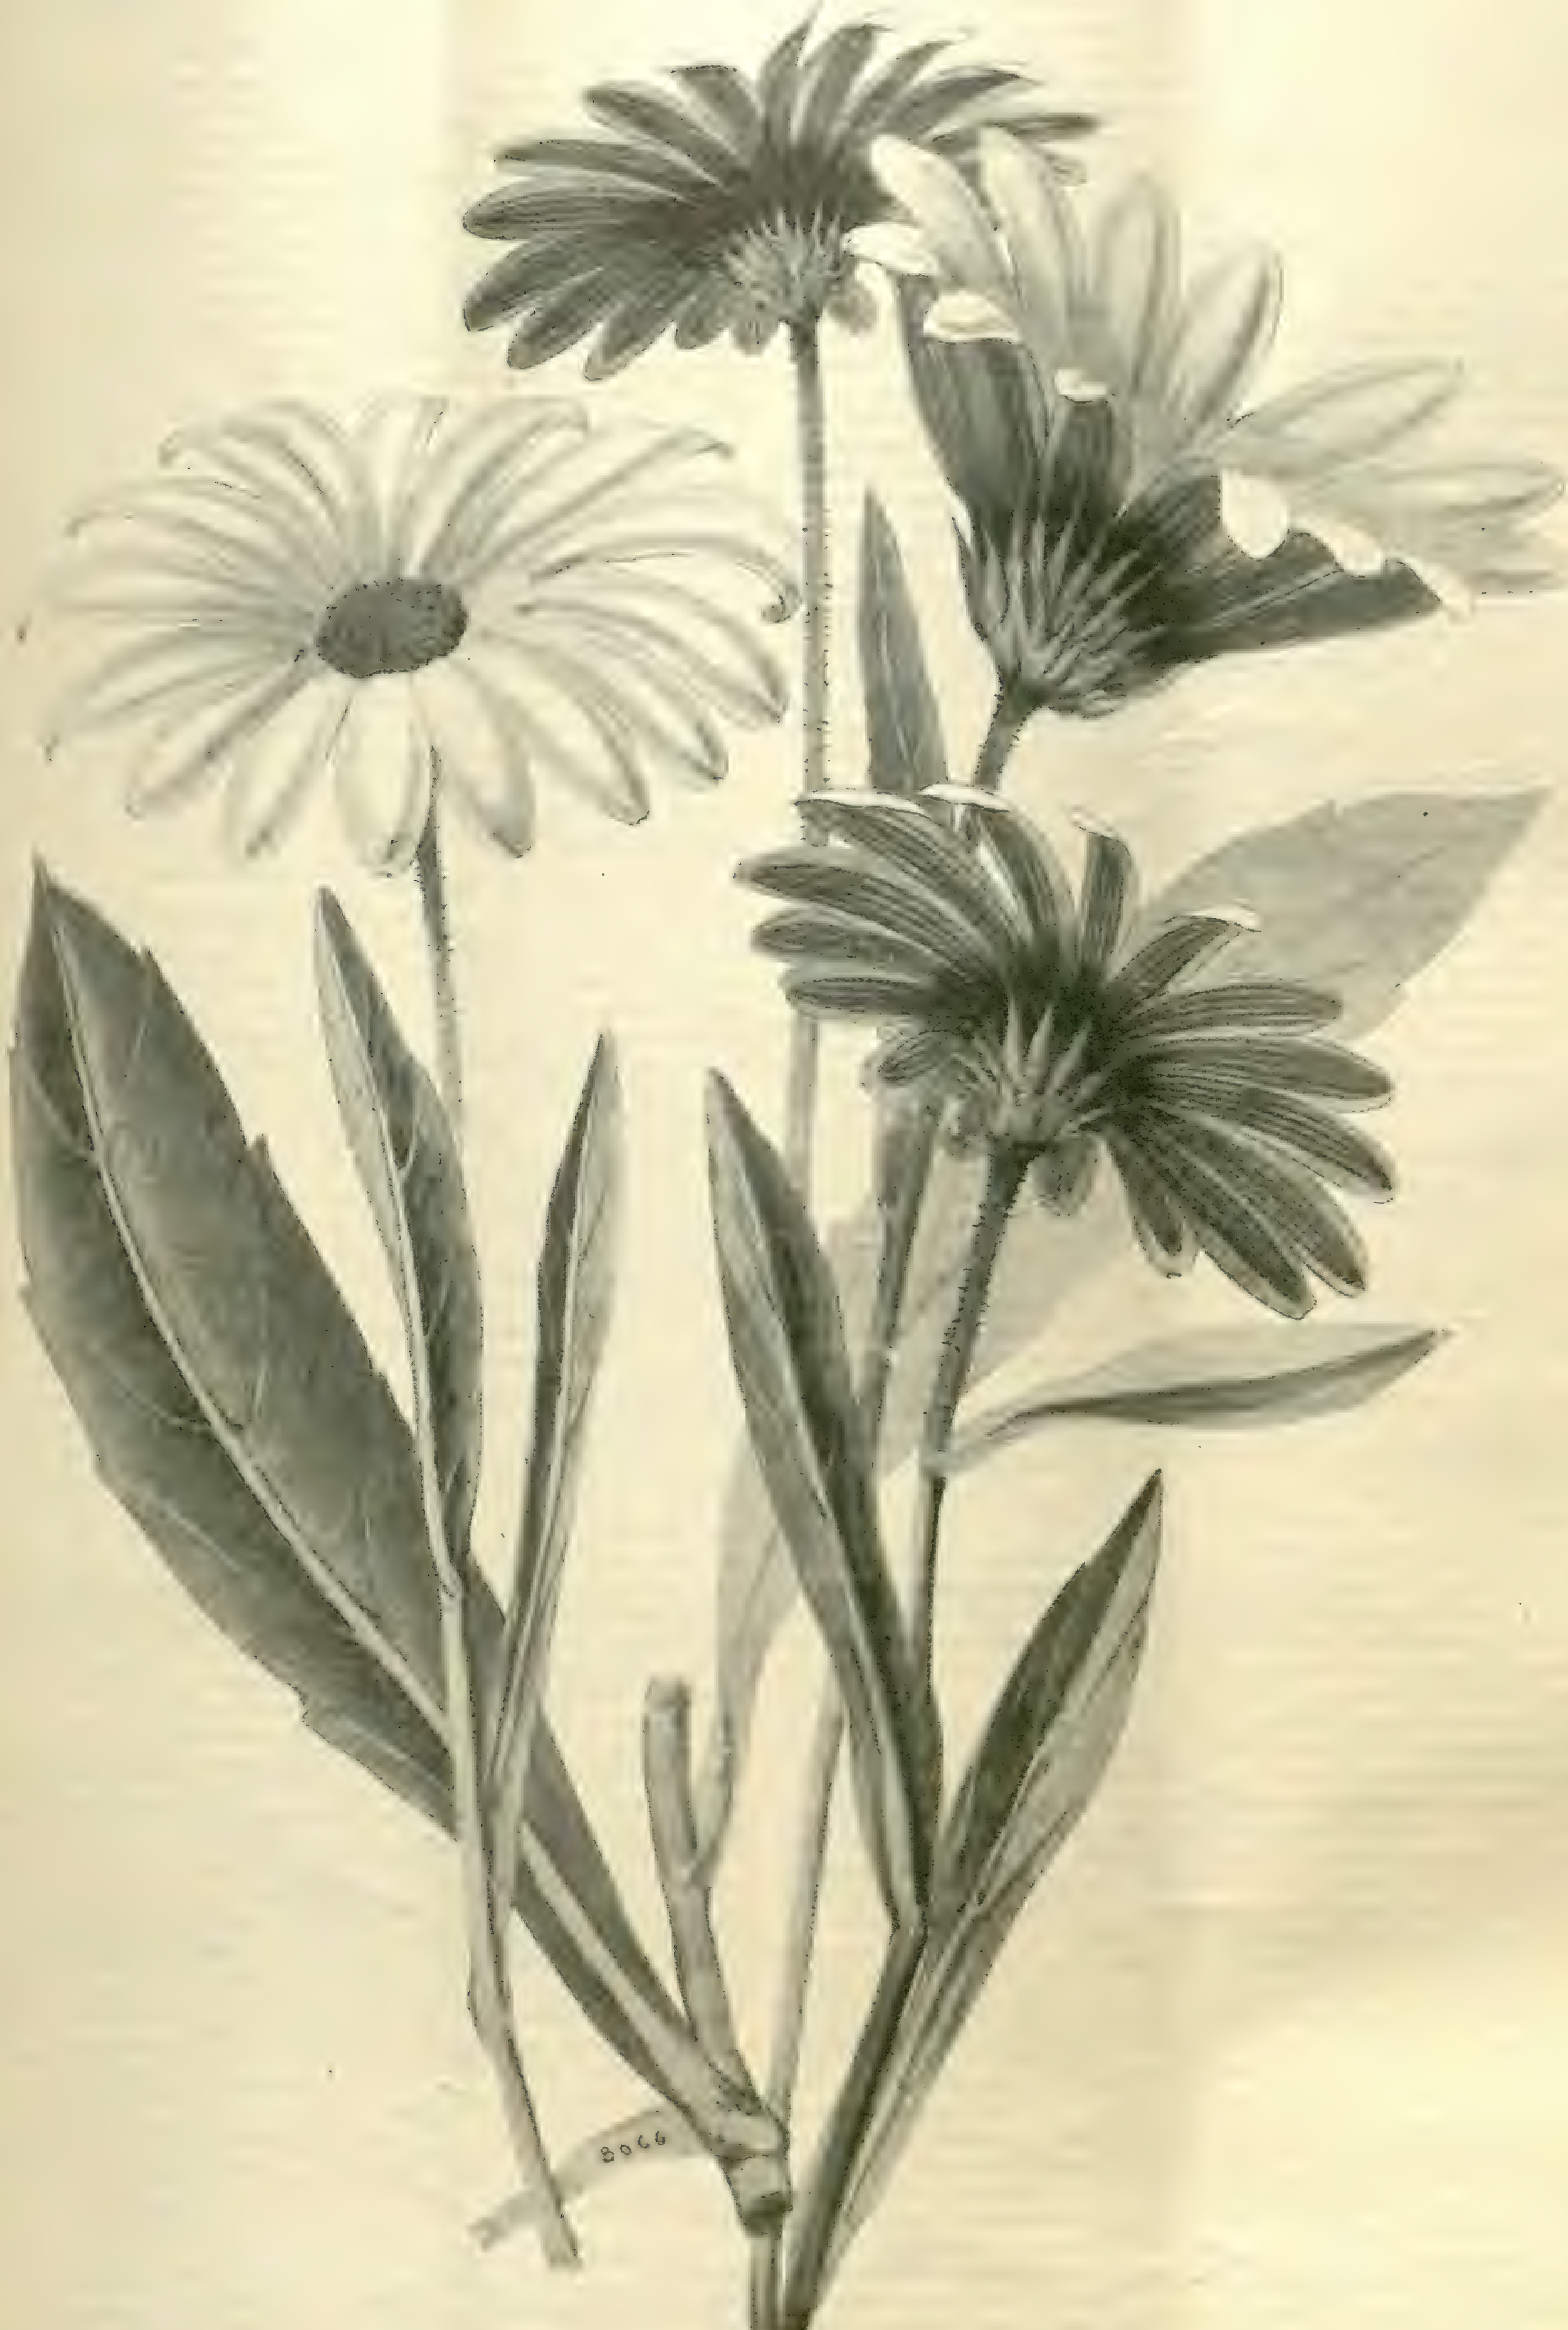
Crops of Potatos.—I observe your "humorous" correspondent "Lux" has been gibing mildly at Mr. Prinsep with respect to potatos, and I notice he seems to have inferred that Mr. Prinsep had grown a crop of from thirty to forty tons per acre. I do not understand that he said anything of the sort; what he did say was that to grow a couple of hundredweight from a pound of seed tubers (as was done in the Hooper competition some years ago) was one thing, but to grow from thirty to forty tons per acre was quite another. I should think it was. I have often read of wonderful crops of this nature, but have never seen them; Thirty tons per acre, some seven and a half bushels per rod! Who has ever lifted so much? Four bushels per rod is a very heavy crop as all know. A greater crop would be one of gigantic tubers, fit food for cattle, but not for man. The famous Hooper competition referred to, for the heaviest produce from single pounds of new American potatos, did result in the production of marvellous crops, but these were obtained quite artificially, subjecting the tubers to warmth and moisture, propagating the shoots, or cutting and obtaining from a single pound some seventy to eighty plants, and growing these in rich deep soil, and producing huge tubers. It is very well to say in such case that it represented forty tons per acre, but to assume thereby that any ordinarily planted crop will produce one half that bulk, would be ridiculous. With respect to size of sets, I like always to select just what I prefer for planting when the lifting of the crop takes place in the autumn. Then I gather up the handsomest tubers I can find, that range from two to three ounces. It has been shown in Surrey that two-ounce sets give the best average results, because in planting them there is less waste than is the case when larger sets are employed. No set needs more than one good stout shoot. That is enough for all purposes, and that one stout shoot a two-ounce set will give as strong as will one of six or more ounces.—A. D.

VEGETABLES FOR EXHIBITION.

Summer Onions for Exhibition.

DURING the last few years very great strides have been made in the production of exhibition onions, which now form one of the attractions at our vegetable shows during summer, autumn, and winter. No exhibitor will stand much chance of winning in a class for a collection of vegetables (onions should be included in all collections, large or small) unless he can put up large, handsome, well-ripened bulbs. In addition to the improvement made in the varieties now grown, the cultivation is now also much better understood. In the first place the site for the onions must be selected during early autumn, and a light, airy, open spot should be chosen. It is not at all necessary to change the ground for this crop annually, as on the same piece of ground I have successfully grown our exhibition onions for some years with a visible improvement each season. In endeavouring to produce fine exhibition bulbs, the following conditions must be secured: (1) A very rich deeply-trenched soil, (2) sowing the seed early in the year under glass, and (3) giving the young plants every encouragement before planting out. As to the time of trenching up the ground, much depends on the nature of the soil one has to deal with. On all kinds of light soils this is best done in the autumn, but when it is stiff and heavy, the top soil should be forked up to the depth of about ten inches in the autumn and left in a quite rough state, the trenching being delayed till quite the end of February or the beginning of March, and only done in fine weather. Too much manure can hardly be applied, and nothing is better than that from the farmyard, but on heavy wet land, burnt garden refuse, road scrapings, or old mortar rubbish should be liberally added. The trenching must be thoroughly done, at least two feet six inches deep, better still three feet, breaking up the bottom, on which should be placed from five to six inches of the longest of the manure, putting another layer of the shorter material about ten inches from the top. I am aware many people advise keeping the lower soil at the bottom, but this I consider a half-hearted measure, and aim at making the whole depth of soil good; this cannot surely be accomplished when the lower spit is kept buried from the air and the action of the weather. This applies especially to the onion bed when intended to be kept as such for some years. Whether the trenching be done in autumn or spring, no attempt should be made to break up the soil, but leave it in as rough a state as possible and apply a good coating of soot and lime as soon as finished. Leave in this state till the first or second week in April (or as soon after as the weather will allow) and then prepare to plant out. Fork over the ground to the depth of about eight inches, breaking up all lumps as finely as possible, add another slight dressing of soot and Smyth's fertiliser, rake down neatly and mark out the rows and alleys. The beds should be formed from eight to ten feet in width, and the rows should be fifteen inches apart, allowing one foot from plant to plant. Nothing is gained by overcrowding. Boards should be used to walk on when planting.

Sowing the seed and preparing the young onions prior to planting out, as before mentioned, is of the utmost importance, as from the very first it is necessary to build up strong and sturdy plants. For some years I practised sowing the seed in sixty-sized pots, but I have come to the conclusion that boxes answer the purpose equally well, and they have this advantage, that they are much more convenient, occupy less room, and so many more can be grown in the same space that there is a better selection of plants at planting time. The same kind of boxes as recommended for early peas and beans are very suitable, being two feet in length, one foot in width, and four and a half inches deep. They should be thoroughly drained, using some rough fibrous loam over this to prevent the soil mixing with it. The soil I recommend is two parts good fibrous loam, one part well-decayed leaf soil, and one part of half-rotten horse-droppings, that from a spent mushroom bed being preferable to any other; add sufficient road sand to keep the whole porous. The soil must not be used when wet, but should be placed under cover some time previous to use. The whole should be passed through a quarter-inch sieve, and then filled into the boxes to within half an inch of the top, making it quite firm. The seed should be sown thinly, and just buried with the finest soil; press down firmly with a smooth piece of board, and well water in. From the 1st to the 10th of January is the best time for sowing, and a vinery or peach house just started is an ideal place for raising the seed, but, failing this, a greenhouse or pit will answer very well. I have seen very fine onions grown by a cottager who had no other convenience for raising the seed and nursing on the young plants than his own cottage window and a small home-made cold frame. The seed was sown in six-inch pots, raised inside the house, and the seedlings placed outside on the sill when the weather was favourable; when large enough the plants were pricked out in the cold unheated and carefully attended to till planted out in April, the result being fine exhibition bulbs. This grower (who is a large prize-winner) has practised this for years, and I mention it to prove the old adage which applies to gardening as to other pursuits, "where there's a will there's a way." As soon as the young plants are above the soil and can be handled no time should be lost in pricking them out into other boxes, using the same kind of compost, but adding a six-inch potful of [illegible] to every bushel of soil. No chill must be given at this stage, and it is better to perform the work in the temperature in which the plants are growing. The strongest and best plants should be selected, lifting them with a pointed stick and putting them in with a dibber at a distance of three inches apart all ways. Continue to grow them in a temperature of about 55 to 60 degrees, and as near the glass as possible, syringing frequently. In bright weather shade if necessary to prevent flagging. After and otherwise give every encouragement to quick sturdy growth. After the plants become well established stir up the soil between them with a pointed stick and remove to a light and more airy position, a [illegible] brick pit being the best place. Syringe twice daily and admit abundance of air when the weather will allow, removing the light altogether on



DIMORPHOTHECA ECKLONIS. (Flowers white and blue.)

favourable occasions. A cold frame should finish and harden off the plants prior to planting in their final quarters, and the lights placed over them only in rough bad weather.

The second or third week in April is the time for planting, and the young onions should be carefully lifted and planted with a garden trowel, disturbing the roots as little as possible in the already prepared soil. The soil should be pressed very firmly about them and water given if the weather is dry. Syringe overhead two or three times a day till the plants become established. For the first two or three weeks the soil should be stirred very shallow between the plants, after which a good mulching of sifted horse droppings to the depth of two inches should be applied. Water freely in dry weather and damp overhead frequently. About every ten days apply a slight dusting of some reliable artificial manure and soot in equal quantities. This is best done in the evening in showery weather. As a rule the onion fly is not very troublesome to these early sowings, but it is always well to keep a few plants in reserve, and to remove and replant without delay any that do not start away satisfactorily, or that show the least signs of being affected. It is a capital plan to pot on a few of the plants from the boxes into five or six inch pots for this purpose, so that when planted they will receive but little check. Sometimes mildew will make its appearance, and in a short time seriously damage the whole bed. This must be constantly watched for. It generally appears in one place first, and unless stringent measures are speedily adopted to arrest it, it will in a few days spread to the whole of the bed, and growth will be seriously checked ; therefore not a minute should be lost in trying to stamp it out. Cut off and carefully remove and burn every affected leaf, and dust thoroughly with fine slacked lime and black sulphur.

If all goes well, I venture to say no crop cultivated in the kitchen garden will give more pleasure during the growing season than the onions. Except to keep the beds free from weeds by hand pulling, and to give thorough waterings in dry weather, nothing further in the way of labour will be required till growth is completed, which should be by about the middle of August. Before finally lifting, the most promising bulbs should be partially lifted with a small hand fork, which will help to ripen, and prevent them splitting should the weather be wet. Choose a fine day for selecting and lifting the crop. Much care is necessary in handling the bulbs ; indeed, too much pains can hardly be taken so that they are not bruised or damaged in the slightest, or they will not keep in a sound condition for any length of time. Exhibition onions ought to be handled as carefully as ripe peaches, for the largest and best are the least likely to keep well when damaged. In finishing off the ripening it is absolutely essential that they should be kept dry. I have found the most ready way of accomplishing this is to place the bulbs in boxes holding about a dozen each, which should be half filled with wood wool for them to rest on. These can easily be moved from one place to another, and during fine weather they should be stood out in an open sunny position, bringing them under cover at night. During wet days a cool, airy vinery is a suitable place, or failing this, a cold frame will answer, if kept well aired. The bulbs should be turned daily, so that every part becomes exposed. After this has been thoroughly done the bulbs should be cleaned, only removing the loose skins. Pare off the roots neatly, and shorten the tops (leaving about six inches), which should be tied tightly at the end with fine twine, then store away in a cool dry room till wanted.

Onions for exhibition should be large, small necks, thoroughly ripened, and of good shape. Without doubt the finest type for exhibition, is the true form of Ailsa Craig (one of the finest onions ever raised), which ought to be globular in shape. I prefer to arrange the bulbs with necks upwards in green moss, edged with parsley.

Autumn-sown or Winter Onions.

This is a most useful and important crop to grow either for exhibition or ordinary use. To grow these successfully, the ground must be prepared as for the summer crop and the onions planted thereon from the seed bed very early in the spring, indeed on the very first favourable chances. Many practise growing the onions where sown, and for ordinary purposes this will suffice, but for exhibition, I am fully convinced much better results will accrue when transplanted to a well-prepared piece of ground. Generally speaking, among amateurs and cottagers, the seed is sown too early, consequently much of the crop runs to flower in the spring. Two sowings should be made, one about August 20, and another about a week later. In mild weather and on light soils, the latter sowing will often prove to be the best. A piece of ground selected in the open for the first sowing, and a south border for the last is advised. It should be deeply dug but not manured, and the bed should be made very firm and dusted well over with soot and wood ashes, finely sifted. The drills should be nine inches apart and the seed sown thinly, when little other attention will be required, except occasional hoeings, till the spring, when the strongest and best plants should be lifted carefully with the trowel. Plant firmly and hoe about them frequently for the first month, when they should be top dressed with sifted old mushroom bed manure and kept well watered during dry weather. For spring and early shows such onions are indispensable, and form one of the most important and telling dishes of vegetables. They are never expected to be ripened off for the earliest shows, and the outside skin only should be removed. The bulbs should be large, clear, and of good shape, and arranged on a large dish, facing them up nicely like cauliflowers and garnishing with parsley. Such onions never keep well for any length of time, so that it is not advisable to grow them extensively. For late shows the spring sown ones should always be exhibited in preference, but when classes are made for both, which is often the case, the bulbs should be ripened off and exhibited in the same way as the summer ones.

Unless required for any special purpose in large quantities, generally sufficient onions for pickling can be selected from the general bed sown in the spring, but to ensure them in quantity, the seed should be sown thickly on a poor piece of ground about the end of April.

Potato onions are hardly worth notice, being very little cultivated now. They should be planted on a good piece of ground, fifteen inches from row to row, and ten inches apart, and moulded up in the same way as potatos. The crop should be lifted and stored in the root room, about the end of June.

Varieties of Onions.

There are now, as with many other kinds of vegetables, a large number of very excellent varieties of onions in cultivation, but I will mention those only which I have proved to be first-rate in each section. For spring sowing and for general crop, James' Long Keeping, though an old variety, still holds its own as one of the very best. True to its name, it is one of the very best keepers. Another very excellent kind is Veitch's Main Crop, of splendid quality and a good keeper. Improved Reading is also a fine variety. For exhibition, without doubt, Deverill's Ailsa Craig is far and away the best ; well-grown specimens of these are a pleasure to look at, both growing and on the exhibition stage. Deverill's Cocoa Nut is also a fine onion, of good quality and very handsome, but not so large as the preceding. These globe-shaped sorts, when well presented, will always find most favour with experienced judges, and rightly so. Among the flat types, Deverill's Lord Keeper, Deverill's Anglo-Spanish, Sutton's A1, Cutbush's Barnet Hero, Carter's Record, and Cranston's Excelsior, are all grand varieties, and each worth growing. No doubt there are others equally as good, but these have specially come under my notice. For autumn sowing, white Leviathan is a grand onion for the early shows. It produces bulbs of great size and I have grown it myself twenty-one inches in circumference. Unfortunately it is a bad keeper and should not be largely grown, but when well arranged on the exhibition stage, it is of excellent appearance and very [illegible]. Blood Red Rocca, when true, is grand for exhibition, and can be depended on for later shows more than the above. Lemon Rocca is also a distinct and valuable addition and comes in well for late spring shows. There are many others, but the three named will be found quite sufficient for any garden. For pickling purposes, the old Silver Skinned is still the most popular.

Aldenham House Gardens. E. BECKETT

DOUBLE WINTER STOCKS.

THE chief value of the winter stocks, the Brompton, and the Queen types, is, that when they pass in safety through the winter, they bloom in spring before the summer varieties are sufficiently advanced to display their flowers. It is, therefore, usual to sow the seeds in July or August, plant out in September or later, as the case may be, to stand the winter. The difficulty of keeping the plants in safety through the winter is great, unless they are on a warm dry border, through which water passes away freely ; and then, when a dry time sets in in late spring or early summer, the plants will suffer greatly. The stock is a soft and succulent plant, it may be said to be of a tender character at all times, and when a mild growing autumn lasts nearly up to Christmas, and is followed, as frequently happens, by drenching rain, with sharp frost close on its heels stocks suffer, especially when they on moist heavy land.

One of the most useful of the winter stocks is that known as the Queen, with which the Brompton type is often confounded. In fact there are two types of the Queen, both somewhat dwarf, and free from change ; one having the flowers borne on short stems and therefore more compact on the spike ; the other with the blossoms more broadly spread from the spike. In the case of each of these types there is generally a good proportion of double blossoms. The true Brompton stock is of tall and strong build, not branching out as do the Queen type, but producing only one stem, generally strong and of considerable length. When such stocks produce large double blossoms, they are very fine, but the percentage of large full flowers of this character is small.

Suggestions have been made as to the adoption of means to secure doubleness in stocks, but it is doubtful if any of the prescribed means, when applied, really conduce to this end. Multiplication of the petals appears to be the general cause of doubleness in stocks. Some botanists suppose that the act of doubling is due to a mere excess of development, and that is doubtless the reason why, in selecting plants for seedling, those blossoms are preferred which appear to possess more than the normal number of petals. It is matter of general knowledge that double forms are more frequently found among cultivated plants than wild ones, and when, as sometimes happens—though the occurrence is remarkably rare—a wild primrose is found to have become double, it usually appears in the case of a plant showing excessive vitality. But it is said that starvation will produce the same result, though the florist is aware of but very few cases indeed of such a cause producing doubleness in blossoms : indeed, his general experience is in the other direction, viz, that the starvation of plants usually producing double flowers will frequently cause them to become single. Dr. Seemann has mentioned an interesting fact, the great preponderance of double flowers in plants derived from the northern hemisphere, when contrasted with those procured from the southern ; and this seems to point to the effect of cultivation in [illegible] the flowers. The stock illustrates one fact, namely, that when the disposition to form double flowers is established from any cause, the tendency becomes hereditary. "There are races of stocks," says Dr. Masters, "in which, out of hundreds of plants, scarcely one double-flowered form is met with ; on the other hand, when the tendency is set up, single flowers become the exception." The soil in which stocks are grown may, if what is known as the plethora theory be set up, have a direct influence on doubling in a nutritious, strong loam, well and deeply dug and manured, at the same time possessing enough of sand to assist the roots in running freely in it ; the Brompton stocks flower freely and [illegible] producing noble spikes of bloom when the blossoms are fully [illegible] Given good soil and careful selection of blossoms for seed purposes, the tendency to double may be hastened. Let it not be forgotten that seed must come from single flowers, as the double blossoms do not produce any

R. D.

WORK FOR THE WEEK.

COOL ORCHIDS.

CYMBIDIUM LOWIANUM and its hybrids should now be flowering, but any that have not produced spikes, but are producing young growths, may be attended to. C. eburneum and C. Mastersi that have gone out of flower will also require attention. These orchids dislike root disturbance, and should not be repotted unless it is really necessary. The old compost should be carefully picked out with a pointed stick, taking care not to damage the fleshy roots; and the new material given should consist of good fibrous loam, lumpy peat, and chopped moss, with plenty of rough charcoal, broken crocks, and silver sand to keep the soil sweet. The material must be well worked down between the roots and made moderately firm, keeping the surface of the soil a little below the rim of the pot. When the potting is necessary, a good shift should be given that will suffice for two or three years; the old pots should be broken with a hammer, as the plants will have so filled them that it is difficult to extricate the roots without injury. The warm end of the cool house suits cymbidiums admirably, insect pests being less troublesome here than in a higher temperature. Water should be sparingly afforded after root disturbance, but a plentiful supply will be needed when growth is free. Plants of the brilliant Sophronitis grandiflorum are now rooting from the growths that have just flowered, and all that require repotting or top-dressing should be taken in hand, using a compost of peat and sphagnum in equal parts. Cochlioda Noezliana, C. vulcanica, and C. rosea are also sending out new roots, and should have fresh material given them; if a shift is needed, pans or baskets should be used, and these suspended from the roof. Cochliodas delight in a liberal supply of water during the growing season. The singular Epidendrum (Nanodes) Medusæ, the flowers of which last a long time in perfection, is now starting to grow, and should have new material afforded it. It does best in well-drained baskets suspended from the roof in the coolest position, and delights in a plentiful supply of water all the year round.

The present is a suitable time to attend to the repotting of Maxillaria grandiflora, M. venusta, M. luteo-alba, M. præstans, &c. They should be grown in pots or pans three parts filled with crocks, using a compost consisting of three parts sphagnum to one of peat. Care should be taken in the watering of the newly-potted plants, giving only sufficient moisture to keep the moss alive until they have become well rooted, when they should have a plentiful supply. The odontoglossum house will be found the most suitable place for them. Trichosma suavis should be repotted, if necessary, as root action has commenced; rough fibrous peat, fresh sphagnum, and a little fibrous loam, with silver sand added, will suffice over good drainage. When in active growth they must be kept moderately moist, and should never be allowed to become dry at any season, as they have no thick fleshy pseudo-bulbs to support them. The beautiful Odontoglossum Uro Skinneri is now producing flower spikes, and will also require attention, repotting or resurfacing any that require it, for new roots will soon appear from the partially-developed growths. Green and black fly is sure to be troublesome in the cool houses at this season, especially on the young growths and flower-spikes of odontoglossums. A sharp look out should be kept for thrip, and on the first discovery of these insects the house should be fumigated with XL All vaporiser; it is the safest plan to fumigate under the directions issued rather than over, as odontoglossums are more liable to injury from fumigation than most orchids. A calm night should be chosen for the operation, taking great care that the foliage is quite dry; the atmosphere, however, should be fairly moist, as the fumes are then more effective. The temperature of the cool houses should be from 50 to 55 degrees by night, with the day temperature of 58 to 60 degrees, and a further rise of five degrees with sun heat. Damping should be done as previously advised, and ventilation given freely on all suitable occasions.—E. SHILL, *New Hall, Hey, Gardens.*

STOVE PLANTS.

SOME of the old stools of poinsettias should now be placed in the propagating house, or where a brisk temperature is maintained, so that they may push into growth for the purpose of affording cuttings. Syringe them freely overhead and amongst the pots, but afford water sparingly at the root. When the shoots are from three to four inches long cut them from the plants with a small heel of old wood attached, and insert them singly into thumb pots containing a mixture of equal parts of loam, cocoa-nut fibre refuse, and leafsoil, with a good admixture of sand, also surfacing the pots with sand, so that when the dibber is inserted some of the latter may fall to the bottom of the hole for the base of the cutting to rest upon. Plunge the cutting pots in a brisk bottom heat, be careful not to keep the soil too wet, and syringe overhead occasionally with warm water, also when water is afforded to the soil see that it is at a temperature approaching that of the plunging material. Another method of propagating them is by cutting up the ripened portions of the stem into lengths of two or three joints and inserting them thickly in pans or six-inch pots, but the first mentioned is the most satisfactory, and with care very few cuttings will be lost. It will be time enough to start the main batch of plants for cuttings the third week in April, as the plants resulting from these, if well attended to and not given a check, will afford splendid bracts on stems from one and a half to two feet high. Euphorbia jacquinæflora requires the same treatment as poinsettias, excepting that three cuttings should be placed in each pot, to be potted on when rooted without dividing them.

Eucharis specimens which it is desired to split up may now be attended to; turn them out and shake all the soil away, sort the bulbs into their various sizes, the largest bulbs to be placed five in each eight-inch pot, six of the next sized in similar pots, and so on. A few of the largest bulbs might be potted singly into six-inch pots, as when flowering such are very ornamental for vases in rooms. A good compost for eucharis is three parts loam, and one part leaf-soil with plenty of sand and broken charcoal added. The drainage must be ample, at least one-third the depth of the pot, placing over this moss or good fibrous pieces of loam, then a little of the potting compost, and on this arrange the bulbs, afterwards adding the remainder of the soil; press the soil firm, and leave a space of from one and a half to two inches between the surface of the soil and the rim of the pot for holding water. Eucharis are thirsty subjects, but are very impatient of stagnant moisture; therefore the free escape of water must be provided for. They should never be rested in a cool temperature, but be kept in the stove all the year round. As regards the eucharis mite, I do not think it is so much to be feared as many imply; we sometimes find it in our bulbs, but it does not affect them, as they grow and flower freely, yet they have very little soil in the pots and abundance of drainage.

Put in cuttings of Thyrsicanthus rutilans, inserting them singly in three-inch pots of sandy soil; plunged in a brisk bottom heat they will quickly root. Pitcher plants or nepenthes requiring larger baskets should be attended to, but be careful not to injure the roots, as they are very brittle; the compost requires to be quite open and porous and to consist of good fibrous peat, sphagnum, and sand. Any specimens that are too tall should ere this have had their heads removed, inserted in pots, and plunged in a brisk bottom heat, or they can be notched and massed in the same way as dracænas. Nepenthes require a strong moist heat with shade from sun. Panax fruticosum bipinnatum, P. f. multifidum, and P. f. Victoria may be propagated by cutting up the roots and stems into pieces an inch and a half long; press these into pots of sandy soil and place in a propagating case. These are useful subjects for home decoration. Achimenes which were started a few weeks ago should now be placed in their flowering pots or baskets, using a compost of equal parts peat, loam, and leafsoil, with sand and about one-fifth part of thoroughly-dried cow manure. Achimenes look especially well in baskets, and if there is convenience a few baskets should be made up to be grown in the stove until coming into flower, when they will be better removed to a conservatory or corridor where there is less humidity in the atmosphere. The latest plants of allamanda, stephanotis, and clerodendron should now be started, but see that the old soil is thoroughly moistened through before repotting or top-dressing. All stove plants which have not been repotted and which are now in active growth will be benefited by an occasional application of some good fertiliser. Gloxinias advancing towards flowering will require stimulants. In houses given up wholly to foliage plants, liquid manure in the evaporating troughs will be of advantage to the plants. Large palms in pots as large as it is desirable to afford them, and which it is found difficult to water satisfactorily through the raising of the ball by the roots below, need attention; have rims of zinc about five inches deep placed round the rim of the pot, pressing it about an inch into the pot, and allowing the ends to overlap about three inches. By this means they can be afforded additional top-dressing, and watering is a simple matter.—J. TUNNINGTON, *Ripley Castle Gardens.*

KITCHEN GARDEN.

SELDOM has the ground been in better condition for sowing and planting than during the present month, for the mild winter enabled all digging to be done in good time, and the exceptionally dry weather has been all that could be desired for pressing on with work. The cold winds and frosty nights have retarded the growth of cauliflowers and peas, but where these have not already been planted the first favourable opportunity should be taken advantage of. All small plants, such as onions, lettuce, parsley, &c., must be planted with care, and if the weather be dry should have a gentle watering in the morning that the surface may dry again before nightfall. Potatos may now be planted in most districts. It is, however, well not to be in too great a hurry with these, especially in low-lying districts that are subject to late spring frosts, for when the young growth is cut down it is seldom that satisfactory growth is made afterwards, the tubers being usually small. The distance allowed between the rows of these must greatly depend on the variety and the quality of the ground. Here we plant the early ones two feet six inches, and the strong-growing kinds three feet, which is not too much. April is always a busy month in the kitchen garden, therefore all work that can be done early will prove a great help later on when everything is in active growth. Where making new asparagus beds is contemplated, the work should now be taken in hand; in some gardens it is not necessary to drain, as this is done naturally, but where the land is cold and composed of a stiff loam or clay, it becomes absolutely necessary to make special preparations if fine heads are to be produced. Instead, however, of going to the extra labour and expense of taking out the ground and filling in with rubble, make the beds on the surface by raising them eighteen inches above the surrounding ground. The soil underneath should be broken up to allow as much of the surplus water as possible to pass through in winter, and so prevent the earth from becoming sodden. Those who can afford to wait may sow seed, but where it is necessary to have a supply quickly planting had better be resorted to. It is well to have a stock of young plants always in readiness by making a sowing each season. A sowing of the early kinds of broccoli should be made on a warm border to yield a supply of early plants; the same may be said of such varieties of cauliflower as Autumn Giant, Autumn Mammoth, Early Giant, Pearl, and Magnum Bonum. Brussels sprouts and borecole should also be sown. It is a good plan to sow several varieties of the latter, for should the winter prove severe some will survive; here Sutton's Favourite does well.

Scorzonera is seldom seen except in large gardens, and then it is not always grown well. It is perhaps one of the most difficult roots to bring to perfection, on poor ground, that the gardener has to deal with. Those who have found any difficulty in growing good roots would do well to make holes with a dibber from a foot to fifteen inches deep, and fill them with fine soil, which should be pressed down, sowing three or four seeds in each, afterwards thinning the plants to one at each station. Salsafy may also be grown to perfection in the same way, but where the ground is in good condition there should be no difficulty in growing either of these when sown in drills about fifteen inches apart, and treated in the same way as parsnips. A small sowing of chicory may be made about the middle of the month, but it should be liberally treated, otherwise these early sowings are apt to run to seed. Celery for the main crop should now be sown on a slight hotbed; celery ought not to receive any check from the time the seedlings appear above the soil until the plants are fully grown, for if they do it is seldom the stems are of much worth, being pithy and tough. A sowing should also be made on a warm border where the soil is rich; plants from such sowings are always preferable for late crops. Make sowings of mustard and cress, radishes, lettuce, and other salads, that there may be no blanks. Watering newly-planted subjects requires great care at this time of the year, for when it becomes necessary to do this the nights are usually cold, and if watering be done in the after-part of the day, the temperature of the soil becomes so reduced that the plants suffer seriously. When it is necessary to water, always do it in the early part of the day, that the plants do not suffer thereby. See that the hoe is worked between all growing crops where there are any signs of weeds, as this will not only keep them in check, but will assist in promoting the growth of the plants.—H. C. PRINSEP, *Buxted Park Gardens.*

FRUITS UNDER GLASS.

ROUTINE work in vineries will now occupy much attention, as, once well started, growth is very rapid in the early stages, and prompt attention must be given to disbudding, tying down shoots, fertilising the flowers of shy-setting varieties, and thinning the bunches, as each of these stages are reached. In disbudding, an eye should be given to the matter of overcrowding, as in many cases far too many shoots are left on, and these not always the best placed. No growth should be permitted for which ample room cannot be found without crowding, as weight and finish of crop depends far more on the proper development of the principal leaves than on any other thing. Take Muscats, for instance; and we find that unless we can have fairly large primary leaves and finish them up properly, the fruit is never of the best; and when shoots are crowded in at something like one foot apart, the vines are sure to break weakly and to show poor bunches next year. I use the Muscat of Alexandria as an instance, because some of its inherent failings, such as shyness of setting and predisposition to shanking, make growers particularly anxious to obtain a good show of bunches, and to ensure this, far too many spurs are left on, these leading to an aggravation of the evils mentioned. A good rule as regards stopping is to pinch out the points of shoots as they reach the length which allows them to meet their neighbours without overlapping, and whether this should be at the second, third, or other bud beyond the bunch selected will depend on the distance between the rods. Very good results are sometimes obtained by stopping at one joint beyond the bunch, but with ample room I prefer to leave one or two additional leaves. Whichever leaf is selected for pinching back to there should be no delay in pinching when that point is reached. In modern vineries where the training wires are placed at a good distance from the glass, it is best not to tie down the shoots until it can be done without fear of their giving way at the base; but where the vines are very near the roof they cannot be left so long, and in this case, it is necessary to do the work very gradually, only putting the slightest pressure on shoots of such brittle varieties as Alicante, Gros Maroc, and the like, nothing being more disheartening than to find some of the best breaks hanging suspended by a strip of raffia. Vines in flower should have the atmosphere kept dry about them, damping down should be suspended or only very slightly done, and evaporating pans kept empty, these being necessary precautions, especially when the weather is dull, for with much atmospheric moisture in the house the pollen cannot be freely distributed. Free-setting varieties require nothing further than a few smart taps of the rod about noon, but such shy setters as Muscat Hamburgh, Muscat of Alexandria, Alnwick Seedling, and others must be dealt with more carefully. The best method I have found is for some one with a naturally cool and dry hand to draw the hand gently over the bunch; this method rarely fails to produce a good set. Another good plan is to use a big camel-hair brush, such as is used by exhibitors of chrysanthemums for manipulating their blooms. In houses containing such varieties, it is a great help to have at least one vine of the free-setting Black Hamburgh planted at the coldest end, so that it may distribute its pollen through the house.

Before the vines come into bloom, and as soon as the best bunches can be selected, all surplus bunches should be removed, nothing being gained by leaving them. Where grapes have to be cut and kept in bottles, it is well to bear this in mind when selecting bunches of varieties that show more than one bunch on a shoot, as the general rule to leave the bunch nearest home, provided it be a good one, should not be followed in its entirety; bunches so placed being sometimes too close home to allow of cutting a sufficient length of shoot to reach the water in the bottles. Thinning should be persevered with as soon as ever the berries have reached a suitable size, as they swell quickly at first and soon get beyond the stage in which they can be dealt with properly. I choose the early morning for this work as it can then be carried out with greater comfort to the operator, but of course it is not always possible to confine operations to this period. Watch carefully for signs of red spider, and apply the usual remedy of sulphuring the pipes, taking care to make the pipes as hot as possible previously. This remedy should not be carried out, and will rarely be necessary, until the berries have reached the size of peas, if done before this the strong fumes will cause rust. Another precaution when sulphuring is to be sure and have a little ventilation on the house at daybreak next morning, and gradually increase it, so that the maximum of air is reached earlier than usual that day; this will prevent scalding.

Melons that are showing fruits should have the laterals stopped at one joint beyond the fruits, and as the flowers open they should be fertilised. The more nearly the flowers open together on each plant the better will be the chances of a good set and uniformity of swelling. Should the plants fail to set the flowers on the earliest laterals, or, should these fail to show a good lot of fruit, it will be best to pick off what there are, and encourage a development of sub laterals. The time lost will not be much, and the crop will be a better one by so doing. During the flowering period, and after, keep up a brisk temperature by day, and not less than 65 degrees by night. The bottom heat should also be brisk, so that the plants may grow freely. Sow for succession and for frame plants if these are needed.—J. C. TALLACK, *Livermere Park Gardens.*

Malva crispa.—Many of the mallows are very beautiful subjects for the decoration of the glasshouse, and for the most part are herbaceous perennials. The species named above is an annual, and is well worth a place in the sub-tropical garden or shrubberies. It is vigorous in growth, attaining to the height of six feet or more, forming an erect pyramid of densely-packed, broad foliage, the margins of which are beautifully curled, and of a pleasing shade of green. Seed may be sown in March on a gentle hotbed, and when the seedlings are large enough to handle they should be pricked off into small sixties and grown on freely. Afterwards gradually harden off, and by May they will have become strong plants for transferring to the position they are to occupy for the summer. I know of nothing so suitable for packing such fruits as strawberries, figs, and thin soft fruits for travelling long distances as the leaves of this mallow, for they are soft as silk, and the curled edges of the leaves appear to me admirably suited to the purpose, preventing, as they do, the fruits when packed rubbing against each other; in fact, they are a boon, for they have no equal. If a piece of rather poor ground can be spared near the packing shed on which to sow the seed, so much the better, for they will then be close at hand to furnish supplies. Sow the seed rather thickly, that the plants may not attain large dimensions, for the small leaves will be of more service than large ones for the purpose named.—H. T. M., *Stoneleigh.*

Double Cinerarias.—These beautiful flowers do not seem so popular as their merits deserve, for they are far preferable for cutting than the single forms, whereas for furnishing they last in good condition much longer. I do not despise the single varieties, as these are extremely useful for conservatory or greenhouse decoration and materially assist in keeping a bright and effective display all through the months of winter and spring. The double-flowered varieties are just as easy to cultivate as single ones, and may be either grown from cuttings or raised from seed. When one has a good colour or an extra fine form it should be propagated and this can easily be effected by offsets obtained from the base of the plant. If the specimens, when flowering is over, are put into a warm moist house they will soon emit young shoots which can be removed and propagated in the orthodox way; after these have rooted grow them in a cold pit, potting them on as they require it till they fill a seven inch pot; after this feed them with liquid manure, and as soon as the flower heads are showing give them about half a teaspoonful of Standen's manure each, as this will help them very considerably. Their greatest enemy is aphis, and this should be kept away by fumigating with XL All vapouriser. I have enclosed a few blooms which were produced from seedlings raised from Messrs Carter's strain. Most of them are now over, but at Christmas I had a a most splendid double white, which I am propagating. It had flowers as large as a golf ball, and these so numerous as to nearly cover the foliage. We find the double forms useful in a variety of ways, and they are as a rule much admired.—W. A. COOK, *Compton Basset.*

THE CINCHONA IN INDIA.

QUININE is principally obtained from the bark of trees and shrubs belonging to the genus Cinchona. Indeed, till about twenty-seven years ago it was hardly known that it was obtainable from any other genus; but it was then ascertained that the bark of an allied genus, Remijia, also yielded it, although in smaller proportion. In 1880, and for several subsequent years, when cinchona bark was scarce and dear, and quinine selling at famine prices, remijia, or Cuprea Bark, as it was commercially called, was imported from South America for the European quinine factories in very large quantities; but later on, when the markets became stocked to overflowing with the rich cultivated cinchona barks of India, Ceylon, Java, South America, and other countries, prices fell, and the importation of Cuprea Bark became unprofitable, and, consequently, ceased. The price of quinine is now so low that it would hardly pay the manufacturers to work up remijia, with its small proportion of alkaloids, even if they got it for nothing; for the expensive manipulation of a large quantity of bark, to get only a little low-priced quinine cannot be a profitable operation. Owing to over-production, the price of both cinchona bark and sulphate of quinine has fallen so low, that the planters get actually less for the bark than it costs them to grow and market it, whilst the quinine-makers can hardly have fared much better; but the fever-stricken millions of the malarious parts of India and other hot countries reap the benefit; and to benefit them, rather than either planter or manufacturer, was the avowed object of our Government in introducing the cinchonas to India and other countries. The results have exceeded the most sanguine expectations, for the introduction has been the means of bringing the price of quinine so low as to place it within easy reach of the very poorest. It is one of the few medicines of foreign manufacture that the natives of the East, almost without exception, implicitly believe in, and their confidence in it is likely to continue whilst quinine remains so cheap that there is but little temptation to adulterate it. Many substitutes have been from time to time put on the market, but not one has stood the trial test, and quinine is likely to remain, as it so long has been, the only safe specific for malarial fevers.

Formation of Cinchona Plantations.

With regard to forming cinchona plantations, Mr. J. A. Gammie, who has recently retired from the charge of the Bengal Government plantations, a charge extending over thirty years, told the members of the Horticultural Club that the planter in the East has no convenient nurseryman to indent on for his plants as his brother at home has, so must raise his own, and, in fact, do everything for himself, from the making of bricks to the building of factories and fixing machinery. In Sikkim there were, practically, but two methods of raising plants practised, viz., by seed and by cuttings. In the earlier years of the enterprise seed was not obtainable, and plants had to be raised from cuttings, which was done in the ordinary way. There were three main species to deal with: C. succirubra, or Red-bark; C. officinalis, or Crown-bark; and C. calisaya var. Ledgeriana, or Yellow-bark. Usually ninety-five to one hundred per cent. of the succirubra cuttings rooted without any trouble, but officinalis was not so accommodating, although not very troublesome, and Ledgeriana was almost a complete failure, but of many and many a batch of it not a single cutting rooted, and seldom more than five to ten per cent.

There was nothing peculiar either in the way the seedlings were raised. The seed was sown in long, narrow, terraced beds, protected by low thatched roofs from rain and sun, but open at the sides for free admission of air and light. The seedlings were kept in the same sort of protected beds, with several transplantings, as they grew and required more room, till six or nine inches high, when advantage was taken of a spell of dull weather to remove the thatch and get them inured to the weather previous to planting out in the plantation. The sites selected for plantations were on the steep mountain slopes, at elevations lying between one thousand and five thousand feet, flattish ground being avoided, as cinchonas cannot long endure stagnant water at their roots; and artificial drainage, however elaborate, does not do much good with a yearly rainfall of one hundred and twenty to two hundred and fifty inches. On the selected sites the jungle, usually consisting of a mixture of trees, bamboos, and shrubs, is cut close to the ground, and great care taken to leave nothing uncut to ensure everything dying and drying together, otherwise there might be an imperfect burn which would entail extra work in the final clearing. The cutting is best done in December, after the dry season has fairly set in, and the burning in the end of March, when the weather is hot and dry. After the ground is cleared, roads have to be traced and made, and pegs put down in straight rows at the distance apart it is proposed to plant, usually four to six feet each way. Then pits of about two feet across and nearly as much in depth are dug out, and afterwards filled in with the same soil mixed with any convenient decayed vegetable matter, and on those little mounds the plants are firmly planted, one at each peg, after the soil has been well saturated with rain, and the sky is overcast. At the time of planting, the seedlings are usually from twelve to fifteen months old, counting from date of the sowing. For three or four years the ground between the plants has to be kept fairly free of weeds, and occasionally dug over. Afterwards but little cultivation is necessary, as the plants will be covering the ground and able to take care of themselves.

Varieties of Cinchona.

When the first plants were large enough to yield bark suitable for chemical analysis, it was found that the Red Bark, whether from seed or cuttings, was fairly uniform in quality, and of the typical character, *i.e.*, rich in the inferior alkaloids, cinchonidine, and cinchonine, but rather poor in quinine. So it was only a question of expediency whether the plants were raised from seeds or cuttings, the result in alkaloids being the same. It is not a good bark for quinine making, but is, perhaps, the most useful to the ordinary druggist for his [illegible] and other preparations. The Crown Bark was also uniform in quality and true to type, however raised. It is one of the very best barks for the manufacture of sulphate of quinine, as it is rich in quinine, and comparatively poor in the other alkaloids. It thrives to perfection in Travancore and other parts of southern India, but is rather a failure everywhere in the more northern Himalayan regions. Its stem bark will yield from three to six per cent. of its weight of sulphate of quinine. The Yellow Bark behaved quite differently. The cutting-raised plants, [illegible] of course, yielded bark of exactly the same composition as the parents, but the seedlings differed in the most perplexing way, both from their parents and from each other. The better sorts yielded from eight to ten and even sixteen per cent. of sulphate of quinine, but the inferior sorts, which were quite as numerous, or perhaps more so, less than two. To make matters worse, the good [illegible] quite indistinguishable from most of the bad till the trees grew up and yielded bark, and not always then even. The original seeds, from the Andes, yielded just as mixed a progeny as the Indian grown did in later years. They were [illegible] in Bolivia for a Mr. Ledger by his half-caste servant, who was afterwards killed for having procured them for export, and thus destroying the monopoly of so valuable a product to its native country. These seeds were first offered for sale by [illegible]

Ledger to the India Office, who refused them, not knowing that they were of any special value, or that they differed from varieties of calisaya already in India. Ultimately they were divided between a Madras private planter, for his plantation on the Nilgiris, and the Dutch Government, for their plantations in Java. Part of the planter's share was afterwards exchanged with the Madras Government for other sorts of cinchona seed, and, through an old friend, I got a very small packet, from which we raised eight hundred plants. These were the parents of most of the Ledger plants, since grown in India and Ceylon, for the species did not thrive on the Nilgiris, but speedily died out, and the Dutch were careful to reserve the Java-grown seeds of the better varieties for their own use for many years. But till the first-grown bark was analysed, neither the Dutch nor English had any idea of the value of the prize they possessed, and till the trees flowered the species even was uncertain. The first flowering specimens were submitted to the late John Eliot Howard, the famous London manufacturer of the purest sulphate of quinine ever put on the market. Mr. Howard had made a special study of the genus cinchona, and published extensively on both its botany and chemistry, and was for many years a trusted adviser of Government on the introduction of the cinchonas to India, in which he took the keenest interest. So, altogether, he was in the best position to determine the species. He pronounced it to be a variety of calisaya, and named it Cinchona calisaya var. Ledgeriana. A few years later Moens, the superintendent of the Java plantations, who was a most excellent analytical chemist, but made no pretence to any knowledge of botany, raised it to specific rank under the name Ledgeriana; and Dr. Trimen, of Ceylon, agreed with him.

But there can be no doubt, I think, that Howard was right, and his name ought to stand. At any rate, the Government of Bengal adhere to it. It is a most variable plant in foliage and habit of growth, as well as in the colour of its flowers, which vary from pure white to bright pink. After the general flowering of the trees, chemical analyses showed that those with white, nodding flowers, and small seed-capsules, were rich in quinine, whilst those with pinkish flowers, however slightly tinged, or with straight flower-stalks or large seed-capsules, were poor; but as there is rarely a rule without an exception, it turned out that the very richest of all in Java had pink flowers. But with this notable exception, so far as I know, the rule holds good that the white-flowered varieties are rich in quinine, and the coloured poor. For instance, a mixed sample of bark collected under my own personal supervision from twenty trees bearing white flowers, but differing more or less from each other in foliage and habit of growth, yielded eight per cent. of crystallised sulphate of quinine; whilst a corresponding sample, collected at the same time and place from twenty trees, with flowers tinged pink, yielded but 2·93 per cent., or nearly two-thirds less; so the formation of plantations, consisting of the rich varieties only, became a matter of the first importance, for it cost no more to grow a rich sort than it did a poor, and the yield of quinine would be more than doubled.

Artificial Propagation.

To ensure this increased yield with any degree of certainty some plan of artificial propagation was necessary, as the seedlings often came untrue to type, and sometimes were a very mixed and inferior lot indeed. Attempts at propagation by cuttings had ended in failure everywhere, and layering was a slow and unsatisfactory process. The other obvious plan was grafting, but that in the ordinary way was slow and expensive, as it had to be done under glass-roofs; so in the end, in Sikkim, we had to do the best possible with selected seed, and give up artificial propagation, much to our regret. But in Java, where the climate and soil are much more favourable to cinchona growth, plants grafted under glass, and afterwards planted out in the open, made good growth, and yielded profitable returns on the expenditure.

A good many years ago, a private planter from Java, a Mr. Weinschenk, told me of a discovery he had made in open-air grafting, by which, according to his account, he got excellent results. In fact, he claimed by it to have almost no failures, and very little expense. But to this I cannot further testify than that I tried his plan on a small scale, but under favourable circumstances, with results that inclined me to view it with favour. His plan was very simple, but new to me. He commenced by making his graft sick, as he phrased it, by ringing its base, and letting it remain on the parent tree till its leaves became of an unhealthy colour, when he cut it off, and fixed it on the stock in the usual way. His whole discovery lay in making his graft sick beforehand, which, to me, appeared a very absurd procedure, but it really may have some reasonable foundation. Perhaps some one will be good enough to give the plan a trial with fruit and other trees at the proper season of the year, and chronicle the results. It should be done when the plants are in active growth. Mr. Weinschenk was a man of many theories, one of them being that the bark of the cinchona, and not the roots or leaves, had the predominating, if not the entire, influence in the chemical conversion of the sap into the different alkaloids. Once when I was with him on a visit to the Nilgiri cinchona plantations he asked the late Mr. M. A. Lawson, then superintendent of the Madras Government plantations, but formerly Professor of Botany at Oxford, and consequently well acquainted with vegetable physiology, where he thought the controlling chemist was located—whether in the leaves, or in the roots, or where? Mr. Lawson answered, off-hand, "In the leaves, of course." "How is it, then," said Mr. Weinschenk, "that if I cut over a plant of C. succirubra and graft on it C. Ledgeriana, which I let grow to some height, then behead and graft on a C. succirubra top, when I shall have C. succirubra leaves and C. succirubra roots, but the bark on the Ledger part of the stem, however many years afterwards, and however much it may have increased, will still be normal Ledger bark, and in the same way the C. succirubra bark at top and bottom will continue to be of the typical C. succirubra character, *i.e.*, the Ledger bark will continue to contain a large proportion of quinine and but little of the inferior alkaloids, cinchonodine and cinchonine, and the C. succirubra *vice versâ*. Therefore," said Mr. Weinschenk, "I maintain that the controlling chemist is neither in the leaves nor in the roots, but in the bark itself." Of course, the obvious weak link in this chain of argument is the fact that the bark on the Ledger part of the composite tree was started while it bore Ledger leaves. But I think it is suggestive of possibilities of getting branch sports by the engrafting of other bark, and that the bark may really have a large influence in determining the nature of the alkaloids, or the colour of the flowers, or in other ways. It is just possible that some of the inexplicable branch sports may have originated in the accidental engrafting of bark from kindred species or varieties.

(*To be continued.*)

Lonicera fragrantissima at Spye Park.—This honeysuckle has flowered [illegible] profusely at Spye this season, and the big bushes have bloomed continuously for several months; the flowers are used in a variety of ways—even for sprays and [illegible] work; indeed, they have been in great request owing to the lovely perfume they emit. This species deserves to be more generally grown, for as yet it is comparatively rare in gardens.—W. A. COOK, *Compton Basset.*

THE HARDY FERNERY.

As hardy ferns are now preparing themselves for the summer campaign by generally reawakened root activity, and a swelling and pushing of the crowns prior to sending up their annual crop of plumes, it behoves their owners without further delay to overhaul them, and see that when they do arise in all their glory they may do so under the most favourable conditions. Undoubtedly their vital energies are so invigorated by the long rest they have had that they will now stand almost anything in the way of division and disturbance with impunity; and as there are no delicate fronds to damage, such operations as repotting and dividing leave no lasting mark throughout the season, as they are very likely to do later on. With the deciduous species the ragged stumps of last year's fronds can be neatly trimmed away, but with the evergreens, such as shield ferns, hartstongues, and blechnums, it is certainly better to leave those fronds which are still healthily green until the new growth has well risen; the old fronds will then speedily lose their vigour, the vital forces of the plant being then directed to the new ones; but there is little doubt that ere this stage is reached the cutting off of green foliage impoverishes the plants. All brown portions, however, can be cut away with impunity. Pots which have been sunk in the ground to obviate risk of winter drought through forgetfulness can now be lifted, washed, and reinstated, intrusive worms or other vermin being removed, and a little mulching of fresh soil introduced if needed.

When numerous crowns have developed division is beneficial, since the frondage of isolated crowns is always much more finely developed than where several are fighting for root-room with each other, quite apart from the fact that the fronds when mixed up cannot possibly show to advantage. The best way to perform this dividing operation is to shake the plants out, and, carefully avoiding any pressure on the growing centres, force the crowns apart with a blunt wedge, unless, as often happens, they can be pulled asunder with the fingers. Sometimes the attachment is so strong as to yield to neither method. Then, if the growing centres show a decided indentation between them, a sharp knife may even be used to part them, though it is not advisable to pursue the cut beyond the actual fleshy connexion, but, this severed, to pull the crowns apart, the individual roots often interlacing, and the fewer of these which are cut the better. Young plants produced as bulbil offsets are almost invariably wedged off, and come away with their little bunches of roots all ready for planting. Some ferns, the shield ferns especially, produce bulbils on the fronds, and many varieties which are not called proliferous, occasionally have one or two near the base. These, if the variety be a desirable one, can easily be reared into plants by cutting the frond into small sections bearing the bulbils, and inserting these in good soil or cocoa-nut fibre, and keeping them close and moist. It is always worth while when cutting off the old fronds to look out for these, since even when stuck round the edges of the pots, they will usually root and form acceptable little gifts later on to admiring visitors. Ferns with running roots or rhizomes, such as the polypodies and bladder ferns, are best left alone if good specimens are wanted, the P. vulgare varieties especially taking a long time to form established plants. If necessary, however, they may now be divided up into as many plants as there are growing eyes, care only being taken to see that a portion of rhizomes are attached to give a fair start. The oak and beech and limestone ferns grow and spread very rapidly, and a pan of leafy compost dotted over with divisions of these just buried in the soil, become a thing of beauty and a joy for the summer in a very short time.

Out of doors it is not wise to be over neat as regards old fronds and leafy débris which may have collected about the crowns until March's drying winds have spent their fury. These afford great protection, and their premature removal may lead to a sudden check and do much harm. Under glass, where all choice varieties should be, even of hardy ferns, everything may be made as neat as possible, and, for the reasons given, the sooner the better, handling now doing no damage. Spores of good things may now be sown with advantage, and if there be a warm corner available, they will come on all the quicker there. It is early yet to talk of white fly and similar pests, but it is well to bear in mind that the eggs are now on the fronds if the vermin have had a chance of depositing them last season, and that the right time to fumigate and clear the house is after these eggs have all hatched, and before the flying stage is reached, between which two epochs there is a period of several weeks. To wait until flight betrays their presence is simply to permit a second batch of eggs to be laid, after which no fumigation can be as perfectly annihilative as with the first brood. Take a fly-bitten fern and watch it so soon as the sun gets a little power in April, and presently tiny white or greenish larvæ will be found. Wait a bit, however, give them a fortnight or three weeks at the outside, there are still unhatched eggs which smoke will not affect. Then fumigate, and quite probably the entire brood will be disposed of for the season.

In arranging pot ferns in conservatories or ferneries proper, take care to have every plant within easy reach. It is always those in the background which, from lack of inspection, form the breeding grounds of vermin, or, failing this, get dry sooner or later. "Out of sight out of mind" is a very solid fact as a rule, and, to avoid the risk, the nature of the, as yet, unrisen plants must be considered, since pots which now appear fully visible may be utterly eclipsed in a month or two by some rapidly growing neighbour. Small varieties, then, to the front, and robuster ones behind should be the rule, especially as, when once the plants start into growth, it is not well to shift them about from place to place, as so doing is very apt to result in distorted fronds due to changes of light aspect.

CHAS. T. DRUERY, F.L.S., V.M.H.

The Fruit and Vegetable Canning Industry has advanced by leaps and bounds in the United States of America, until at the present time it employs upwards of sixty thousand persons and represents an invested capital of thirty million dollars, equal to six and a quarter million pounds sterling.

THE WATER GARDEN.

PLANTS AND PLANTING.

HAVING previously referred to the best methods of constructing various forms of water gardens, both on a large and on a small scale, I will now deal with the necessary preparations for planting, and will also enumerate the most suitable plants. In the case of water in the rock garden, where a comparatively small pond or stream would probably have to be dealt with, these preparations would naturally differ from those required for water gardens on a bolder scale. As cemented ponds will seldom be made more than two and a half to three feet deep, the best way to deal with these is to form (with rough dark stones) irregular enclosures, to be filled up with leaf mould, peat, loam, &c., to within a foot of the intended surface of the water. Planted into these irregular submerged beds aquatics of all descriptions will thrive far better than if merely sunk in baskets or pots. Quite near the margin some of these beds might be filled up, so that the surface of the soil is only four or six inches below the surface of the water; these situations would be admirable for plants loving to be only partially submerged like Typha minima, menyanthes, the Bog-Arum, and others. Large ponds as well as small ones should, if at all possible, be so constructed that by opening a valve the water can be lowered at will, or even drained off altogether. This greatly facilitates planting operations, and enables one to clean out a pond, or check the growth of, or abolish, certain water plants. In the case of planting waterlilies and other aquatics into large ponds it would be well to deposit on the bottom of such a pond mounds of leafmould and loam, and, when the plants are strong enough, to plant them into large wicker baskets and place them on the mounds previously prepared, so that the crown of the plant is about twelve to eighteen inches below the waterline. The wicker basket will soon decay, but by that time the roots will have penetrated into the good soil below and the plants will flourish as well as could be desired, and will also soon be strong enough to withstand the ravages of water-rats and other vermin. But if the plants are not strong and well developed it would be advisable to grow them during the first season or two in a small tank or basin, or if they must be planted into the large pond to surround them with wire netting for protection.

The arrangement of plants in the water garden must, of course, depend entirely on circumstances, such as the number of plants available, the size of the pond, stream, bog, or whatever form of water garden is to be planted. The laying down of hard and fast rules for arranging water plants is, of course, impossible. This is as much a matter of taste as the painting of a picture. But the laws of colour and harmony that apply to the artistic grouping of other ornamental plants are the same here; such grouping should never be conspicuous, and should appear to be Nature's work rather than that of man. It has already been pointed out that it would be absurd to cover the whole of the water with plants. Irregular groups of flowering aquatics, such as water lilies, will be much more effective than single specimens. Here and there the groups should be separated by a comparatively large expanse of water, and near the shore furthest away from the eye specimens or groups of tall growing plants may be introduced with good effect.

The banks of a pond or streamlet are of even greater importance, with regard to the arrangement of plants than the water itself. Nothing could be worse than an uninterrupted fringe of plants around the whole pond. However thickly we may plant the parts where the land projects into the water, or where, at least, convex shorelines are formed, in some portions, and especially in the concave parts of the bank where the water would form a kind of bay, there should be grass only, mixed here and there with groups of iris and such dwarf plants as would never form an obstruction to the view. In other words, instead of a narrow belt of plants all around a pond, the plants should in some parts be united into large bold masses, in others sparsely scattered, and in still others there should be nothing but the green sward. In the case of a bog-garden by the waterside the best plan is to group the tallest plants at a considerable distance from each other, and carpet the spaces between with groups of dwarfer kinds. Whatever plants we may use for the embellishment of the water garden our arrangement can be picturesque only if we follow Nature, and import to our work something at least of that indescribable wild charm, careless grace and simplicity found in and around natural ponds and streamlets. I will not make any attempt to give anything like a complete list of plants for the water garden, nor can I give any detailed descriptions without exceeding my limits of space. I will, however, enumerate some of the best, which from experience I have found most suitable.

By submerged plants are meant those which, when planted, would have their crowns covered by not less than ten or twelve inches of water. The very first rank among these must, of course, be given to the waterlilies, and as most waterlilies increase so rapidly that they would, in a short space of time, become too large for the small pond of a rock garden, I will here, first of all, name a few of the smallest kinds, but it must be understood that these might also be grown in larger ponds where they would be well in sight and could be protected from fast-growing varieties. In a like manner many of the plants here classed as "large waterlilies" might with advantage adorn the small pond of a rock garden for at least several years until they become really too large, when they might be either reduced or transplanted to a larger pond.

Exeter.

F. W. MEYER.

DISOBEDIENCE IN THE ARMY is looked upon as one of the gravest crimes a soldier can be guilty of, and in the past it has often been punished with death. The fate of a battle and the lives of thousands of men, let alone our national honour, have often been dependent upon the prompt carrying out of what might have seemed a trivial order. Discipline without good health, however, would be like a house without a foundation; therefore great pains are taken to keep our fighting men free from disease. Holloway's Pills have always been found an excellent medicine for this purpose, as, in addition to cleansing the blood, they invigorate and give tone to the system.—[ADVT.]

EXHIBITIONS AND MEETINGS.

ROYAL BOTANIC SOCIETY, March 30.

FOR once in a way the fates were kind, and the spring show at Regent's Park was held during delightful spring weather. We sincerely hope that such good weather will be dispensed to the society at all its 1898 exhibitions and fêtes. There was a bright display on this occasion, but almost entirely composed of trade exhibits; indeed, considering the lack of competition, it is a wonder that the R.B.S. offer prizes at all. Spring flowers were greatly in evidence.

COMPETITIVE EXHIBITS.

The first prize for a collection of hardy spring flowers was secured by Mr. T. S. Ware with pans of Primula obconica, P. verticillata, Muscari botryoides, and M. b. alba, Orchis pallens, Androsace carnea, Orphrys speculum, one of the Bee orchids, chionodoxas of various kinds, Epigæa repens, Hepatica triloba cærulea, Trillium grandiflorum, Fritillaria meleagris, hardy cyclamen, primroses, saxifragas, adonis, and a few other subjects all in flower.

The St. George's Nursery Company secured the chief award for twelve cyclamen with handsome specimens in twenty-four sized pots. The first prize for hardy azaleas was secured by Messrs. Morle and Co., Finchley-road, with forms of A. mollis; Mr. Kemp, Barnes, second. Mr. J. Mowbray, gardener to the Hon. H. C. Legge, Slough, secured first prize for a dozen cinerarias with large specimens. For orchids Mr. G. Cragg, gardener to W. Walker, Esq., Winchmore Hill, secured first place with Cattleya Shilleriana, Cypripedium Rothschildianum, Oncidium sarcodes, Ada aurantiaca, Cattleya Trianæ delicata, and Phaius grandifolius. Messrs. Morle and Co. were awarded a second prize for hyacinths.

The silver Daffodil Cup offered by Messrs. Barr and Son for the best collection of cut daffodils, polyanthus forms excluded, was won by Mr. W. J. Grant, Bassaleg, Monmouth, with an interesting collection of about sixty varieties; some of the most notable forms were Glory of Leiden, Emperor, Johnstoni, Empress, Sir Watkin, Figaro, Poeticus, Præcox grandiflorus, Albicans, W. J. Goldring, Gloria Mundi, Mrs. Langtry, J. B. M. Camm, Odorus, Mrs. Walter Ware, King of the Netherlands, Backhousei, Katherine Spurrill, Horsfieldi, and Hume's Giant.

TRADE EXHIBITS.

Messrs. B. S. Williams and Son, Holloway, were large exhibitors, staging a fine batch of brilliant-flowered clivias, including the leading varieties. Forced lilacs and Azalea mollis flanked a big group of amaryllis, the varieties Dr. Masters and Gerald Balfour being especially noteworthy. Orchids were well represented by odontoglossums, cœlogynes, and specimens of the charming Phaius Norman. Messrs. J. Laing and Sons, Forest Hill, had an extensive display of flowering and foliage plants; Dracæna Goldieana, caladiums, Leea amabilis, boronias, cytisus, azaleas, clivias, acacias, yellow and white arums, heaths, tree pæonies, palms, and crotons, not forgetting some brilliant streptocarpus, combined to make up a good display. Clivias, Azalea mollis in variety, spiræas, ericas, mignonette, Primula obconica, and liliums were tastefully associated with ferns, palms, foliage begonias, and other useful and charming palms by Messrs. J. Peed and Sons, Norwood. Mr. G. Kelf, gardener to Mrs. Abbott, South Villa, Regent's Park, put up a large group of miscellaneous plants suitable for conservatory decorations; deutzias, azaleas, tulips, lily of the valley, hyacinths, narcissi, dielytras, heaths, &c., were the principal subjects associated with palms and ferns. Messrs. W. Cutbush and Son, Highgate, had a conspicuous group of acacias, [illegible] eriostemons, Magnolia Soulangeana, Richardia Elliottiana, Souvenir de la Malmaison carnations, boronias, diosmas, &c.; this was a most attractive exhibit.

A beautiful display of daffodils was arranged by Messrs. Barr and Son, Covent Garden; Sir Watkin was well represented, and so were Horsfieldi, Weardale Perfection, the new bicolor form named Victoria, princeps, C. J. Backhouse, rugulosus, Incomparabilis Stella, maximus, and tortuosus; these were all cut blooms. In pots they had Horsfieldi, Emperor, Empress, Victoria, Madame Plemp, Santa Maria, Grandis, J. B. M. Camm, Cernuus, Golden Spur, &c. The whole display was good and the flowers remarkably fine. The St. George's Nursery Company, Hanwell, set up a big group of finely-grown cyclamen representing a first-rate strain both as regards colour and habit; a large white form shown by this firm deserves a special mention for its size and substance. A big regiment of stalwart hyacinths from Messrs. W. Paul and Son, Waltham Cross, secured a large share of the general admiration; the spikes were invariably [illegible] and full, and the foliage dwarf, deep green, and bright; there were specially [illegible] developments of Koh-i-noor, pink; Von Schiller, rose pink; La Grandesse, white; Jacques, blush; and City of Haarlem, yellow. The Messrs. Paul [illegible] staged a group of fragrant roses, the leading varieties being the wonderful and perpetual Enchantress, Madame Jules Grolez, and Madame Abel Chatenay. In addition to these displays a large exhibit of camellias in considerable variety came from Waltham Cross; both plants and cut flowers were staged. Another [illegible] of cyclamen came from the Church Road Nursery Company, Hanwell; all the specimens were well grown, but the rich purple form was conspicuous by reason of its brightness. Narcissi, both cut and in pots, were largely exhibited by Mr. T. S. Ware, Tottenham. Sir Watkin, Obvallaris, Grandis, Victoria, Alexandra—a fine new ajax form of rich yellow colour; Empress, Maximus, Spurius, and [illegible] Leedsi and Barri forms were shown in good condition.

A handsome group of orchids was staged by Messrs. Hugh Low and Co., Enfield; it included some charming odontoglossums, O. luteo-purpureum being very good; Cymbidium eburneo-Lowianum, Dendrobium Boxalli, lycastes, [illegible] Odontoglossum Edwardsi was conspicuous over all. One of the [illegible] exhibits was that of lily of the valley, shown by that great master [illegible] of cultivating them—Mr. T. Jannoch, Dersingham. Mr. Jannoch [illegible] pyramids and pans of this popular flower, and in every case the spikes [illegible] and stout, carrying from ten to fourteen large, pure white, fragrant bells. [illegible] A. W. Young and Co., Stevenage, were exhibitors of cinerarias. [illegible] Messrs. W. Rumsey and Son, Waltham Cross, came in for a large [illegible] tion, and were greatly appreciated; Maréchal Niel and Niphetos [illegible] largely represented. Messrs. B. S. Williams and Son, Holloway, [illegible] of daffodils, bouquets and crosses of roses, stocks, and lily of the valley; a chaplet of cycad foliage and white lilies was a simple and effective production. Mr. H. B. May sent a few ferns; Asplenium ornatum, Doryopteris [illegible] Lomaria ciliata major, a grand plant; Pteris longifolia Mariesi, Davallia [illegible] maxima, and Gymnogramma Mayi, a sulphur form, were the leading kinds.

Messrs. J. Laing and Sons had a large table of floral arrangements, [illegible] bouquets, sprays, and crosses; the firm is taking a special interest in the [illegible] tion of these works of art, and have made a special department [illegible] bouquet of roses and cross of red roses and white stock were most successful, [illegible] were some of the sprays. The exhibit displayed a great variety of designs. [illegible] Edmonton, [illegible] extensive exhibit of ferns from Messrs. J. Hill and Son, pleasing relief to the bright daffodils, &c. Some big specimens of nephrolepis, Alsophila excelsa, lomarias, &c., were displayed over baskets of smaller examples of the most popular ferns, chiefly adiantums, aspleniums, and gymnogrammas. Varieties of Azalea mollis, shown by Mr. W. Kemp, Ganzale Nurseries, Barnes, were bright and well flowered. Some exceptionally well grown mignonette was exhibited by Messrs. Morle and Co., Finchley Road. Messrs. J. Carter and Co., High Holborn, exhibited a fine strain of cinerarias, both colour and size of flowers being of the best.

MEDALS.

A Silver-gilt Medal was awarded to Messrs. Wm. Paul and Son, Waltham Cross, for their combined exhibit.

Large Silver Medals were awarded to Messrs. J. Hill and Co., Messrs. Hugh Low and Co., Mr. Kelf, gardener to Mrs. Abbott, Messrs. J. Laing and Sons, Messrs. B. S. Williams and Son, the Church Road Nursery Company, Hanwell, and St. George's Nursery Company.

Silver Medals were won by Mr. T. Jannoch, Messrs. J. Carter and Co., Messrs. W. Cutbush and Son, Messrs. J. Peed and Sons, and Messrs. Barr and Sons.

Bronze Medals were secured by Mr. W. Kemp, Messrs. J. Laing and Sons, Mr. H. B. May, Messrs. W. Rumsey and Son, Messrs. B. S. Williams and Son, Messrs. A. W. Young and Co., Messrs. Morle and Co., and Mr. T. S. Ware.

ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER.

THE first show of the year in connection with the above society took place at the Town Hall, Albert Square, Manchester, on March 15 and 16. Several years ago this show was made up of ordinary spring-flowering plants—hyacinths, tulips, cinerarias, primulas, cyclamens, &c.—but the one this year was mostly orchids, and not of the common types either, but first-class.

Mr. Ashworth, of Wilmslow, had a collection that contained many gems, and included the white form of Dendrobium nobile, D. Wardianum alba in several varieties, especially one named Harefield Hall var., the strong yellow contrasting so well with the white; D. Juno, D. Melanthopthalmum, and many others well worthy of note. Cattleya Trianæ in variety was well represented, and a few cypripedium seedlings came, the result of C. Chamberlainianum crosses. A gold medal was awarded, and several F.C.C.'s and awards of merit were here well deserved. On the right hand side of the hall, Mr. Cypher, of Cheltenham, staged, as usual, a splendid lot of well-grown plants, dendrobiums predominating; D. Schroderianum was very striking, and there were some good phaius, Cattleya Trianæ, Cœlogyne cristata alba, cypripediums, &c., and all well deserved the awards gained, as well as a gold medal. Next to Mr. Cypher, a grand lot of plants was put up by Mr. Robson, of Bowdon, dendrobiums again predominating; D. nobile Fisheri was a gem, having a large flower of a deep colour; D. nobile Robsonæ was good, and gained an F.C.C.; Cymbidium eburneum was also well grown. The group merited a silver medal, though gold medals have been awarded to worse.

On the left-hand side of the hall Messrs. Charlesworth and Co., of Bradford, staged a group of plants, not so large as others before mentioned, but, at the same time, full of good things. Here was represented Phaius Norman, figured in the GARDENERS' MAGAZINE of March 19, in quantity for such a rare thing; this is well worthy of a place in collections, being so rich in colour, and bold. Dendrobiums, odontoglossums, cymbidiums, trichopelias, &c., completed the group. Phaius Norman gained a F.C.C. Mr. Cratrix, West Point, Whalley Range, Manchester (gardener, Mr. McLeod), had some fine orchids, and Cypripedium Harrisianum albens is the best variety seen; Dendrobium rubens grandiflorum gained F.C.C., and was shown amid Lycaste Skinneri alba (a good variety), Dendrobium Amesis, D. Rolfæ, many choice forms of D. nobile, Odontoglossum Wilckeaum (A.M.), Cypripedium leysenianum, C. vexillarium, a cypripedium hybrid the reverse cross to C. Thompson (A.M.), Lælio-cattleya, Mrs. Astor, and other good things. Mr. Lofthouse, gardener to A. Warburton, Esq., Haslingden, staged some good odontoglossums and dendrobiums; Lycaste Skinneri alba was good, and so was Dendrobium cybele nobilius, and to these awards were given. Mr. Stevens, gardener to W. Thompson, Esq., Stone, again brought some of his famous odontoglossums, intermixed with good examples of dendrobiums in variety; a silver medal was awarded. A dendrobium hybrid, obtained by crossing D. nobile with D. thrysiflorum, and something in the way of Wiganæ, gained a F.C.C.; this was from the Walton Grange collection. Mr. Stafford, gardener to F. Hardy, Esq., Tyntesfield, showed hybrids of dendrobiums; D. Clio alba gained an A.M. Some good odontoglossums and cattleyas were shown, Mendeli var. May gained a F.C.C. Mr. Morton, gardener to Mr. Hinchcliffe, Ashfield, Hale, Altrincham, had a very effective group, consisting of dendrobiums, cymbidiums, cœlogynes, cypripediums, &c., well put up with palms and ferns; silver medal. G. F. Moore, Esq., Chardwar, Bourton-on-the Water, showed cut spikes of odontoglossums and dendrobiums.

Messrs. Ker and Son, of Liverpool, had again a splendid collection of amaryllis, some of the finest varieties being Vulcan, Momus, and Imperial; and in the lighter colours, Aphrodite, Minos, Saturn, and other intermediate ones being equally good. Messrs. Dickson, Brown, and Tait, Corporation Street, Manchester, had a fine collection of hyacinths, all the best varieties being represented; daffodils and other bulbous plants also appeared. Messrs. Birkenhead, of Sale, had a fine collection of ferns, stove, greenhouse, and hardy forms, in first-class condition, such as polystichums, polypodiums, aspleniums, athyriums, davallias, adiantums, pellæs, braineas, &c. The scented fern, Lastræ fragrans, proved of great interest. Mr. Bruce, nurseryman, Stretford, Manchester, sent a collection of carnivorous plants, which was of great interest to the public. Mr. Edward Sherwood, Nottingham, had a display of rustic vases. Mr. P. Weathers sent some spring-flowering plants from the Botanic Gardens, Old Trafford; and R. Brown, Esq., sent miscellaneous cut blooms, grown outside at Sunny Hill, Llandudno. Altogether the show excelled those of previous years,

SPRING FLOWERS AT BIRMINGHAM.

A SINGULARLY beautiful show of forced spring flowers was that seen in the conservatories of the Edgbaston Botanic Gardens, Birmingham, on the 15th inst. and following day. For this delightful feature the subscribers were indebted to the liberality of that enthusiastic florist Mr. Robert Sydenham, who furnished all the liberal prizes offered in a dozen classes, besides giving others of a special nature to the largest exhibitors. The spring shows of the [illegible] Society having fallen through, Mr. Sydenham came in to fill the void last year. Then the show was pretty but small, whereas this year it was double the dimensions and the quality really high-class. There were classes for single hyacinths, in dozens and half dozens in pots; of single tulips the same, also in narcissi, and in Polyanthus narcissi; for lilies of the valley, cinerarias, spiræas, collections of spring flowers, and cut narcissi. The competition in each case was capital, showing how numerous and capable are the gardeners and amateurs of the district in growing spring flowers. The banks of tulips, those of the collectors of diverse plants, the superb display of bouquets and floral designs and stands made by Messrs. Perkins and Son, of Birmingham and Coventry, and not least the big bunches of hyacinths, tulips, single and double, narcissi and other bulbs, staged by Mr. Sydenham, gave colour of exceeding brillancy to the show, which was arranged by Mr. W. B. Latham, the curator. Of new tulips Unique, in Mr. Sydenham's group, calls for special notice. It is a white Pottebacker having a gold base and ribs presenting exceeding beauty. Proserpine rectified was also a very beautiful tulip, the white flutings or stripes on the rich coloured petals being of a very refined form. The collection included all the best varieties in commerce. The exhibition was crowded with visitors each day, and clearly demonstrated the exceeding popularity which attaches to early bulbous and other plants when gently forced into bloom.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this society was held at Anderton's Hotel on Wednesday evening, with Mr. T. W. Sanders in the chair, when a somewhat lengthy agenda was disposed of. The most important business of public interest was the election of the Floral, Classification, and Finance Committees, which, by reason of the large number of nominations, occupied some time. The ballot for the members of the Floral Committee was proceeded with, and on the report of the scrutineers Messrs. D. B. Crane, J. P. Kendall, W. H. Lees, J. W. Moorman, H. Cannell, W. Howe, and G. Langdon were declared duly elected. The Classification and Catalogue Committee comprises, under the new rules, fifteen members, and the following were elected: Messrs. H. J. Jones, G. Gordon, T. Bevan, C. Gibson, W. H. Lees, H. Cannell, J. W. Moorman, W. Mease, D. B. Crane, J. Lyne, W. Wells, G. Stevens, M. Gleeson, E. Beckett, and W. Higgs. The members elected to serve on the Finance Committee are Mr. G. Gordon, Mr. G. E. Willis, and Mr. J. W. Moorman.

SUMMER BEDDING.

THE liking for the system of bedding out, which was so popular a quarter of a century ago continues, and many of the materials employed to work out various effects are grown largely in these days and used in much the same way. There are certain persons in the trade who lay themselves out to maintain a supply—a business that can pay only on the assumption, which may be reasonably held, that very large supplies have to be provided. So rapidly and cheaply are various soft-wooded subjects used for bedding purposes produced, that the trade generally find they can purchase popular bedding plants cheaper than they can grow them, and so what is a much larger industry than is generally supposed has been built up. The system which favours the employment of soft-wooded plants in the decoration of the flower garden, in masses, in zones, in segments, and in various mixtures, is one which will not readily die out because of its convenience. There are a very large number of amateur gardeners who have small gardens, and are fettered by limited means of production and expenditure, who find cheap bedding plants of suitable character and easily obtainable, a great boon. No better estimate perhaps can be found of the popularity of what may be termed our common bedding plants, than a study of those who crowd the windows of some of the premises of the firms who have branches in the City at this season of the year. The philosopher will find much in the survey to interest him; the social reformer to encourage him. The majority of them are young men in whose breasts may be the awakening of a desire to cultivate some of the flowers which make an appeal to his better nature.

The first beginnings of many a successful career as an amateur cultivator have doubtless been conceived by the contemplation of a shop window. We like to contemplate the cultivation of flowers as an antidote to grosser things. Such occupations, innocent, interesting, and pleasant, do something towards softening the manners and subduing the mind. It is curious to observe how many of the favourite bedding plants which were popular with the last generation, still hold their own. There is a loyalty in matters floricultural which holds firmly to subjects of proved usefulness and effectiveness. Verbena Purple King is a case in point; for its perfect habit of growth and the agreeable shade and persistence of its colour, it has never been surpassed. Boule de Niege is still a popular white; and Lustrous, which emanated from Salisbury many years ago, our best scarlet. It is so with the Erinus type of bedding lobelia, with the ageratum and that fragrant subject, the heliotrope, one of the most favourite of the latter. Miss Nightingale takes us back to the period of the Crimean War. Among bedding calceolarias, the fifty-year old amplexicaulis is unsurpassed for its peculiar shade of colour, and excessive propagation does not operate to weaken the constitutional vigour it has ever possessed. No bedding coleus has ever surpassed the old Verschaffelti, and yet thousands have been raised since its introduction many years ago. The most useful alternantheras were in cultivation when the bedding-out system was at fever height. And then our bedding pelargoniums: the old varieties hold their own, and defy a multitude of aspirants to the seat of honour they occupy. Master Christine, Madame Vaucher, Mr. William Paul, and a few others, take us back to the time when the Pelargonium Society was a power; when Peter Grieve was raising his fine tricolors; Dr. Denny improving the zonals; when the pelargonium held the field, and the tuberous begonia appeared to dispute its supremacy. As a bedder among the tricolors, who shall dare to say that Mrs. Pollock has been surpassed for general usefulness, or the old Flower of Spring and Lady Plymouth among the silver-foliaged varieties. The golden-leaved Crystal Palace Gem is practically without a rival.

There are other sections of plants which illustrate the persistency of individuals, such as Centaurea ragusina and Gazania splendens. There is a remarkable peculiarity attaching to the latter; that while during the prevalence of dull weather in summer the flowers close, they expand freely in autumn, let the weather be ever so sunless. Many other plants employed for bedding can be raised from seeds—the aster, stock, mimulus, Phlox Drummondi, mimulus begonia, annual dianthus, and similar subjects are invaluable; but these many amateurs have convenience for raising. The subject which more than any other restricts the convenience of the amateur for keeping of bedding plants through the winter is the claims the chrysanthemum has upon him. Were it not for this Eastern flower, which can now be had in bloom from July until February, but little else would beautify his greenhouse in autumn. Some of the early-flowering varieties of the chrysanthemum can fittingly find a place in our flower borders from July onwards. Dwarf and compact in growth, they are singularly prolific of bloom and lasting also.

OBSERVER.

CHRYSANTHEMUM LEAF RUST.

THERE is no doubt that the fungus, or rust as it is called, which has lately affected chrysanthemums in this country is one of the troubles which beset plant life that will need constant watchfulness on the part of growers to prevent its spreading seriously. I have found on inquiry that the disease was far more widely distributed last season than most people supposed, and though one heard occasional reports of its existence it did not seem to create general uneasiness in the minds of growers.

Those who are unfortunate enough to find it amongst their plants, however, need not be unduly alarmed, for a rapid and vigorous growing plant like the chrysanthemum should be easily cleared of a parasite such as this. The most important fact to bear in mind is that the reproductive powers of the fungus are very great, as the spores are produced in immense numbers and rapidly distributed. The spores, when seen under the microscope and magnified some 450 diameters, have the appearance of brown seeds, similar in shape to stock seeds. So far as I have observed they do not grow on the stems or upper surface of the leaves, but invariably on the under side.

Though we may have a remedy in the "Bordeaux mixture," or sulphide of potassium or other fungicides, that will destroy the spores, it is evident that we cannot destroy the growth in the leaf itself, hence the best remedy is to pay every attention to the plants to induce a hardy growth and to remove each leaf that shows signs of the rust, if possible, before the spores become distributed elsewhere. All affected portions should be handled as gently as possible so as not to disturb and scatter the spores, and they should be burned. If a collection is carefully examined regularly and all traces removed in this way, there should be no difficulty in stamping it out, but if the fungus is left about the plants it will in all probability prove destruction.

It is commonly reported that the pest was introduced into this country from America on the variety Niveus; if so, it is curious that we have not seen or heard more about it before, as Niveus was sent over in 1893, and has been grown in every collection, and very extensively too, yet we do not become familiar with the disease till 1897-98.

We first noticed it in these gardens last November on plants of Viscountess Hambledon and Souvenir de Petite Amie; every plant was carefully looked over, but little more was found, and this on some bush-grown plants of Golden Gem. Though every particle which we could discover was carefully burned, we have found here and there a spot on the young stock this spring, but I have little fear of being able to eradicate the pest by the repressive measures alluded to. The varieties most susceptible to the attacks of the fungus will doubtless be those which make the most fleshy and succulent leaf growth, or especially those which are unduly fed with manures; so that my usual caution to inexperienced growers against the too free use of manure in the early stages of growth needs special emphasis this year in view of the probable attacks of the fungus.

Through the kindness of Mr. J. W. Odell, of Stanmore, who has sent me specimens mounted as microscopic slides, I have been able to examine both the chrysanthemum rust—Uredo Chrysanthemi—and the rust which infests carnations —Uredo carophyllus. Growers of carnations will probably be familiar with this latter, and the two are possibly identical, for the only difference apparent under the microscope is that those spores taken from the carnation are slightly paler in colour; no difference can be discerned with the naked eye.

It will be interesting to prove this, and Mr. Odell tells me that he has infected the two species with both forms of rust in order to arrive at a satisfactory conclusion. Should they prove to be identical, then the blame of origin may be removed from Niveus, as the rust was well known amongst carnation growers prior to the introduction of this well-known chrysanthemum.

It will be an advantage to know also what is the probable length of time for which a spore will exist on the soil or any place which is unsuitable to its germination. It is possible that experiments may prove the value of fortifying the plants, by means of certain solutions in watering the roots, against the invasion of the spores, and I am sure our editor will kindly find space for the communication of any means which is likely to prove satisfactory in stamping out this fungus.

I have several letters from growers who say that they do not anticipate any serious difficulty in dealing with it, and my object in writing is not to alarm those interested, but rather to put them on guard against the possible increase of the fungi unobserved.

Trent Park Gardens. W. H. LEES.

ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, &c., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning change of dates.

Potatos for Exhibition.—T. O. H., Aberystwyth: Articles on this subject appeared in our issues of March 5 and March 12.

Hardy Camellias.—S. C. G., Farnham: A goodly number of camellias are hardy in the south of England and Ireland, but unless well sheltered from cutting winds they do not expand their flowers properly. The variety to which you allude is probably Camellia Beali, with crimson flowers. This flowers freely out of doors in the south of Devon, Cornwall, and the Isle of Wight, and continues in bloom for about three months.

Exhibiting Primulas and Auriculas.—C. S. H., Hythe: The prizes offered by the National Auricula and Primula Society at the exhibition to be held at the Drill Hall on April 26 can only be competed for by members of that society, or Fellows of the Royal Horticultural Society. If you make yourself eligible for entering such competitions, the secretary of either society will furnish you with full particulars. The R.H.S. secretary is to be found at 117, Victoria Street, S.W. Mr. T. E. Henwood, hon. secretary of the National Auricula and Primula Society, resides at Auricula Villa, Hamilton Road, Reading.

Violets in Frames.—S. W., Portslade: We do not find that the damage was due to fungoid attack in the first instance, but rather that some error of cultivation rendered the tissues so tender that they were laid open to fungoid attack. We have found the best results arrived at by lifting the young violets when well rooted and the crowns plump and firm, and planting them in the frames where they are to remain and flower during winter. Raise the bed and frames, as this allows of better drainage, and violets detest stagnant moisture, especially during the dull season.

Tomatos in Frames.—T. F., Salisbury: There is no difficulty in growing tomatos in frames provided the frame is in a sunny position, and that the plants are strong and sturdy. Do not plant too early, otherwise there may be a difficulty in keeping out frost should such occur. Plant firmly, and towards the front of the frame; then place a board or boards so as to form a slope from front to back, and face the south. On this the plants may rest and be secured loosely, and in such a position they will have the full benefit of sun. Air must be given carefully until the weather becomes settled, after which the lights may be removed for a greater part of the day.

Artificial Fertiliser for Fruit Plantations on Light Soils.—J. L., Oundle: Muriate of potash and superphosphate will prove the most serviceable manures in combination at the rate of one and a half hundredweight of the former and one hundredweight of the later per acre, or even larger quantities if the soil is very poor. One hundredweight of nitrate of soda per acre will assist the trees if they have not been making good growth of late; it serves to stimulate growth, and also by keeping the soil moist it enables fruit trees to tide over spells of very dry weather. Of course, if the soil is very light nothing is better for it than a heavy dressing of rotten farmyard or stable manure both to enrich the land and keep it moist.

Polygonum cuspidatum—W. W., Henley: This plant is not a bamboo, nor has it any affinity to bamboos. It is a Japanese perennial herb that will grow to a height of from four to eight feet, according to the richness of the soil and the supply of moisture during hot weather. It is a handsome species, and grown as an isolated specimen it is very effective. Flowers are produced in summer, they are small, creamy white, and borne in large numbers on a profusion of drooping panicles each four to six inches long. The flowers are succeeded by scarlet fruits. A good dictionary of plant names is Johnson's Gardener's Dictionary, published by Messrs. G. Bell and Co., Covent Garden; price 9s. net. No book contains the names of all plants.

Carrot Fly.—E. G., Ashford: If possible select a piece of ground that was gas-limed early in the winter, and has laid fallow since. Fork over the surface and then make all firm and level. Sow in the usual way, and thin the crop as early as possible; after thinning give the crop a good watering, unless the weather be showery, so as to stop all holes whereby the Carrot Fly can obtain access to the roots and so deposit its eggs. Encourage the crop by hoeing, watering, and other items that make for good cultivation. Mix a quart of paraffin with a medium-sized barrow-load of finely-sifted wood ashes, and use the mixture as a top-dressing both after sowing and as fast as thinning is completed. It will be obvious that thin sowing acts as a preventive, because the seedling carrots do not then raise the ground as when thickly sown, neither is the ground so much loosened at the time of thinning. Watering with soot-water acts as a preventive, and also as a stimulant to the carrots. The great points—after the land has been properly prepared—are to keep the ground firm around the roots and to encourage free growth.

Names of Plants.—Under this heading we can only undertake to name species and specific varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp moss or leaves as packing material to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that the numbers be legible and firmly attached to the specimens. We cannot promise to name more than six specimens at one time from any one correspondent.

D. P., Wickham: 1, Gaultheria procumbens; 2, Abies balsamea; 3, Saxifraga oppositifolia.

F. F., Chichester: 1, a pale form of Dendrobium nobile; 2, Masdevallia triangularis.

S. F. G., Nottingham: 1, Asplenium Belangeri; 2, Nephrolepis rufescens tripinnatifida; 3, Adiantum Luddemannianum.

N. P., Eastleigh: 1, Megasea Stracheyi; 2, Muscari conicum; 3, Clivia miniatum; 4, Forsythia viridissima; 5, Scilla siberica.

Communications Received.—J. L. and S.—M. H. W.—M. E.—R. D. —D. T. F.—R. L. H.—J. L.—W. H. L.—W. P.—H. H. D.—J. B.—G. W.—J. T.—W. N. B.—C. S. H.

The Rating of Greenhouses, &c.—Although the law is, in rude parlance, set down as a "hass," yet it is not so much the law that is in fault when legal judgments vary, and are so inconsistent, as is the interpretation put upon it by those who constitute the legal luminaries of our courts. No doubt very much of this inconsistency of interpretation and of judgment is due also to the phraseology of Acts of Parliament, which, being drafted by lawyers, seem to be so flooded with verbose verbiage that they seem rather to hide their meaning or the intentions of the framers than to exhibit them. Possibly, did laymen draft Acts of Parliament on plain common-sense lines, the lawyers' occupation, like that of Othello, would be gone. If an Act states that market greenhouses are, like agricultural land, partially exempt from rating, there ought not to be the least trouble in understanding that such is the case. But when it is said in two lower courts that greenhouses are so far exempt, and in a higher court that they are not exempt, how is it possible to do other than exclaim "a plague on both your houses"? The High Court of Appeal is, after all, not the highest court, and that seems an absurdity, because the House of Lords is the final determining factor; and it is hoped, if the recent decision of the Master of the Rolls is to be appealed against, that it will be determined by the Law Lords very speedily. Such varying of judgments do not help to attract respect for the law. The sooner a final judgment is given the better.—A. D.

The Gipsy Moth (*Porthetria dispar*) is still proving a great pest in the State of Massachusetts in spite of efforts made to exterminate it. According to Mr. L. O. Howard, of the Division of Entomology of the U.S. Department of Agriculture, the gipsy moth was introduced in 1869 for silk-growing experiments. Some examples escaped, and these settling amid the undergrowth and scrub multiplied slowly but steadily until by 1889 the moth was recognised as a pest that must be seriously battled with. Since that time it has done enormous damage by the defoliation of deciduous trees over an area of 22,089 miles. Many methods have been adopted for its extirpation, and the State has spent on these no less than £151,000, in addition to grants from Congress equal to £8,333. Spraying with arsenate of lead, the use of creosote to destroy deposited eggs, grease banding to prevent ascent of caterpillars, and trapping by means of bands of burlap canvas have been the principal methods employed against the moth, with the result that about nine-tenths of the colonies existing in 1891 have been exterminated. Mr. Howard considers that were it not for the difficulty of dealing with woodland undergrowth, a continuance of the present measures would soon terminate in a complete extirpation of the pest, and one of the greatest experiments in economic-entomology in the history of the world would have accomplished its aim and end.

NEW BOOKS.

Supplement to the Ninth Edition of the Rose Garden. By William Paul, F.L.S., &c. (Simpkin, Marshall, and Co., London).—The supplement to the ninth edition of "The Rose Garden," which has been recently published, is of special interest as a reminder of the fact that the first edition of this justly famous work was published exactly half a century since, and showing the advance made in the improvement of roses during the past decade. The original edition of this work was published in 1848, and it is not surprising it should have created an immense amount of interest far beyond rosarian circles, for it was considerably in advance of the books on the rose that had previously been published, and the author had not reached the age considered essential to the production of books on technical matters that shall be regarded as the highest authorities on which they treat. Since the issue of the first edition, which at once placed Mr. William Paul in the front rank of rosarians, "The Rose Garden" has undergone many improvements, and has been kept fully abreast of the progress made in rose culture; but the original plan has been modified rather than changed, and when we consider the high degree of popularity it has enjoyed throughout the past fifty years, one can hardly fail to be impressed by the remarkable judgment displayed by Mr. Paul at this early period of life. The ninth edition, in which every phase of rose culture is discussed with fulness and exceptional ability, was published in 1888, and the chief object, we are told, in publishing this supplement is to bring the information as to new roses up to date. The supplement, in fact, consists of a selection of roses introduced from 1888 to 1898, and as it comprises those varieties only which are considered most worthy of cultivation, it is of much value as a guide to the roses introduced during the period. Altogether two hundred and twenty-nine varieties are enumerated and described in the selection, and it is interesting to observe that the greatest advances during the period covered by the selection, in rose development, have been in the tea-scented varieties and their hybrids, the polyanthas, and the sweet briars. "With regard to the novelties of the last ten years," observes Mr. Paul in the interesting preface, "there are unquestionably some splendid acquisitions both of sorts suited for the more perfect adornment of the flower garden or for the tables of the exhibition," and no one with a knowledge of what has been accomplished in the improvement of the rose of recent years will be disposed to question the statement. Mr. Paul also speaks of the trend of public taste for varieties that are remarkable more for their freedom and continuity of flowering than for the large size and fine form of their individual blooms, and while he evidently regards the increased popularity of garden roses with considerable favour, he fully appreciates the superb form characteristic of the flowers of varieties that find favour with those who aspire to honours at the exhibitions.

Willing's British and Irish Press Guide for 1898. Price 1s. (James Willing, jun. (Limited), 162, Piccadilly, W.)—When a book has reached its twenty-fifth annual issue, it may be assumed with perfect safety that it has fulfilled its mission, and is appreciated by those who resort to it for information on matters relating to the Press of the United Kingdom. The work has long occupied a place on our bookshelves, and we are consequently in a position to speak from practical experience of the care with which the annual issues are compiled.

MARKETS.

Covent Garden.

The wintry weather has caused a shortening of supplies, so that with a moderate demand prices are fully maintained. Fruit of all kinds finds a ready sale, and there is a slight improvement in the demand for potatos.

Fruit.—American apples, 15s. to 28s. per barrel; Californian Newtowns, 8s. to 12s. per box; English grapes, 1s. 9d. to 3s. 6d.; Belgian, 1s. 6d. to 2s. per lb.; bananas, 4s. to 9s. per bunch; pineapples, 2s. 6d. to 6s. 6d. each; lemons, 5s. to 15s. per case; Canary tomatos, 1s. 6d. to 2s. per tray, 4s. to 5s. per case; Valencia oranges, 10s. to 16s. per case; Jaffa, 9s. to 12s. per box.

Flowers.—Arums, 3s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 2s. to 3s.; Lilium Harrisi, 3s. to 4s.; tea roses, 6d. to 1s.; pink roses, 4s. to 8s.; red roses, 3s. to 4s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 4d. to 9d.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 3s.; Roman hyacinths, 4s. to 6s.; daffodils, 2s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; wallflowers, 4s. to 6s.; primroses, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 9d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. per bunch.

Vegetables.—Seakale, 12s. to 18s. per dozen punnets; celery, 9s. to 15s. per dozen rolls; English, onions, 6s. 6d. to 7s. 6d. per cwt.; Valencia 7s. to 9s. per case; asparagus, 2s. 6d, to 8s. per bundle; French lettuce, 1s. to 1s. 3d.; cos lettuce, 2s. to 2s. 6d.; endive, 1s. 6d. to 2s.; cucumbers, 3s. to 6s. 6d. per dozen; parsnips, 3s. to 4s.; cabbages and savoys, 3s. 6d. to 6s. per tally; carrots, 3s. to 3s. 6d.; green mint, 4s. to 5s. per dozen bunches; Italian cauliflowers, 3s. to 4s. per hamper; rhubarb, 3s. to 4s.; forced, 1s. 3d. to 1s. 6d. per dozen bundles; mushrooms, 6s. to 8s. per 12 lb.; spinach, 2s. to 3s. per bushel; Brussels sprouts, 1s. 3d. to 1s. 6d. per half-sieve; potatos, Canary new, 10s. to 16s. per cwt.; French, 2d. to 3d. per lb.

Borough Potato Market.

Supplies are moderate, and though the demand is not brisk, it has improved during the cold weather. Prices are keeping steady.

Dunbars, 120s.; Scotch Magnums, 100s. to 110s.; Hebrons, 100s.; Snowdrops, 90s.; Bruce, Maincrop, and Sutton's Regents, 90s. to 95s.; Reading Giants and Saxons, 85s. to 90s. per ton; Belgians, 3s. 6d. to 4s.; Germans, 3s. 6d. to 4s. 9d. per bag.

The mean reading of the Barometer during the week at Greenwich was 29·73 inches, and that of the Thermometer 37°·5, the latter being 4°·4 below the week's average in the 50 years 1841—90. The direction of the wind was variable, the horizontal movement of the air being 40 per cent. above the week's average in the 16 years 1860—75. The duration of registered bright sunshine in the week was 16·5 hours. The measured rainfall amounted to 0·56 of an inch.

ENGAGEMENTS FOR THE ENSUING WEEK.

Tuesday, April 5.—Scottish Horticultural Association.

Wednesday, April 6.—Royal Caledonian Horticultural Association Spring Show. Two Days

Thursday, April 7.—Linnean Society.

Saturday, April 9.—Royal Botanic Society's General Meeting.

AUCTIONS.

Monday, Tuesday, and Wednesday, April 4, 5, and 6.—Dwarf Roses, Orchids, and Lilium Auratum, &c., at Protheroe and Morris's Rooms.

SANKEYS' famous GARDEN POTS
Bulwell Potteries, Nottingham.

Messrs. Dicksons, Limited, Chester, write; "The Flower Pots you have so largely supplied us with are light, strong, and well made, and in every respect highly satisfactory."

Messrs. Richard Smith & Co., Worcester, write: "We beg to say that we are highly satisfied with your 'Garden Pots.' They are well made, light, yet strong, and we like them better than any other we have ever used."

Messrs. Fisher, Son, and Sibray, Limited, Handsworth Nurseries, Sheffield, write: "We have pleasure in testifying that after having used your pots for the past twenty-five years, we have found them all that could be desired."

CLAY AND SON, STRATFORD, LONDON, E.

THE WEST'S PATENT IVORINE PLANT LABELS.

The "Ivorine" Writing Disc, which is to be written upon, being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon by a common lead pencil or pen and ink, it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, and does not become unreadable, as is the case with all painted labels as the paint gets old. The copper wire shank may be used as per the illustration, or it may be bent round the stem of a plant, leaving the name showing in the most readable position. For all horticultural purposes.

Samples and Lists of the West's Patent Specialities post free.

Price, **9d.** per dozen; **8s.** per gross, Carriage Paid.

Supplied by all Nurserymen, Florists, &c.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration." G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited)**, 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

Cadbury's
cocoa

ABSOLUTELY PURE,
therefore BEST.

IMPORTANT CAUTION.

Never give your Children Cocoa mixed with alkali, kola, hops, malt, starch, and other adulterations—which simply reduce the value of the pure article, and are in some cases

DANGEROUS TO HEALTH.

Dr. ANDREW WILSON, F.R.S.E. (COMBE AND GILCHRIST LECTURER, &c.), says:—

"If you have a pure Cocoa you want nothing else in the way of constituting it a food, for it contains in itself all the principles which go to make up a perfect article of diet."

CHILDHOOD

CADBURY's Cocoa is absolutely Pure, therefore best for Children. It contains all the Nutritive elements indispensable to growth and development.

YOUTH

CADBURY's Cocoa is a PERFECT FOOD, containing a larger proportion of Flesh-forming and Nutritious elements than any other. It is invigorating and sustaining—promoting hardihood and great physical endurance. The best beverage for Athletes.

OLD AGE

CADBURY's Cocoa—refreshing, comforting, and strengthening in old age. Perfectly safe and reliable, being absolutely Pure and free from Alkali and other mixtures.

Cadbury's
Cocoa
contains in a concentrated form all the *necessary* elements for the formation of Bone and Muscle.
It is
ABSOLUTELY
PURE.

The *MEDICAL MAGAZINE* says:—
"For Strength, for Purity, and for Nourishment, there is nothing superior to be found."

Ask for CADBURY's Cocoa, and do not be put off with quack concoctions that are often sold for the sake of getting extra profit.

OLD AGE requires the most easily digested food, and that which imparts the most Nutriment. CADBURY's Cocoa fulfils these requirements—being a "Perfect Food."

16, FINSBURY STREET; AND ALL SEEDSMEN.

EPPS'S COCOAINE.

COCOA-NIB EXTRACT.

The choicest roasted nibs (broken-up beans) of the natural Cocoa on being subjected to powerful hydraulic pressure, give forth their excess of oil, leaving for use a finely-flavoured powder—"Cocoaine," a product which, when prepared with boiling water, has the consistence of tea, of which it is now, with many, beneficially taking the place. Its active principle being a gentle nerve stimulant, supplies the needed energy without unduly exciting the system. Sold only in labelled Tins. If unable to obtain it of your tradesman, a tin will be sent post free for 9 stamps.

JAMES EPPS AND CO., LTD.,
Homœopathic Chemists, London.

STANDEN'S MANURE.

TRADE MARK.

ESTABLISHED OVER 30 YEARS.

Exceeds all others in General Fertilising Properties and Staying Powers.

Promoting a rapid, healthy, and robust growth to plants generally.

It is a clean and dry powder, with very little smell.

Its highly fertilising properties render its money value, in comparison with other Manures, at least double, very small quantities will produce favourable and lasting results.

117, VICTORIA STREET, S.W.
Feb. 19th, 1898.

DEAR SIR,
Your "Eureka" Weed Killer gave the greatest satisfaction at our Gardens, and we should be glad of another 5-gallon drum of it.

Yours faithfully,
(Signed) W. WILKS, Secretary, R.H.S.
Vicar of Shirley, Surrey.

TRY "EUREKA" INSECT KILLER!
Clears all Insects without Damage to Plants or Trees.
Price List on application.

MANUFACTURERS:
TOMLINSON & HAYWARD,
Mint Street Chemical Works,
LINCOLN.

FOR PLEASURE AND PROFIT

FRUIT

Nothing so profitable and easy to grow.
80 Acres of Saleable Trees.

SEEDS

THE BEST PROCURABLE.
Lists Free.

ROSES

HUNDREDS of THOUSANDS.
Bushes in variety. Packing and Carriage free for Cash with order.
8/- per doz., **60/-** per 100.
All other Nursery Stock carriage forward.

ROSES IN POTS From 15/- a doz.
Ornamental Trees, 91 Acres,
A Superb Collection of Herbaceous Plants,
Four Acres of Glass,
Clematis (80,000) from 15/- doz.
N.B.—Single Plants are sold at slightly increased prices.

GENERAL CATALOGUE
(Over 160 pages) of Nursery Stock, artistically produced containing some hundreds of illustrations, and full of valuable information, free on receipt of 3d. for postage.
Please mention this Paper.

Williams'

SHADING MATERIALS.

THE MOST SUITABLE FOR
SHADING ORCHIDS, FERNS,
Palms, and Stove and
GREENHOUSE PLANTS

WILLIAMS' HOTHOUSE SHADING.

It is a strong, durable Cotton Netting, woven in squares so close as to exclude the direct rays of the sun, but admitting the greatest amount of light attainable through shading.

It will stands the weather better than any other class of Shading, and may be beneficially used on account of the thickness of its texture, during cold weather, to keep the frost out. The leading Orchid and Plant Growers in the country have used this material for some years, and speak very highly of it, pronouncing it to be the very best material for Plants they have ever used.

Blinds made up and fixed complete.

Sold in pieces 30 yards long by 1½ yards wide.
Price **40s.** each. Samples submitted gratis.

WILLIAMS' "EUREKA" SHADING.

This new shading is in the form of a white powder, and is prepared for use by applying boiling water to the compound, and allowing it to cool, when it can be applied by means of a brush. It dries instantaneously, and can be rubbed off easily when moist. This shading may be used for GREENHOUSES, SKYLIGHTS, WINDOWS, &c.

Sold in 1 lb. packets, with directions for use, price **1s.** each.
1 lb. free by parcel post for 1s. 3d.

2 lb. free by parcel post for 2s. 4d.

Each packet will make half a gallon of shading material when mixed. It is a great improvement on anything hitherto offered, and lasts the whole season.

THE GARDENERS' MAGAZINE.

SATURDAY, APRIL 9, 1898.

NOTICE TO ADVERTISERS.

Owing to the continued increase in circulation, the "Gardeners' Magazine" will in future go to press earlier. No advertisement can be guaranteed insertion, or altered, unless received before Four p.m. on Wednesdays.

NOTES OF THE WEEK.

THE GHENT QUINQUENNIAL.

THE opening of the great horticultural exhibition at Ghent on the 16th inst. is, as usual, anticipated with an immense amount of interest throughout Europe, and horticulturists, without regard to nationality, will learn with something more than an ordinary degree of satisfaction that the gathering has the promise of surpassing in extent, in attractiveness, and in interest the most successful of the previous quinquennials held by the Royal Botanical Society of Ghent. The schedule is more comprehensive than on any previous occasion, and contains upwards of seven hundred classes, and these are so arranged as to ensure an adequate representation of every phase of horticulture, as far as it is possible to represent it at this season of the year. As becomes their importance and interest, new plants remarkable for the beauty of their flowers or the ornamental character of their leafage have the first division devoted to them, and as this section includes twenty-four classes the novelties should form a large and highly interesting feature. The enormous development which the cultivation of orchids has undergone of late years is strikingly exemplified, for whereas ten years ago orchids formed but a very small part of the show, no less than seventy-two classes have been provided for these fascinating plants, and the importance of this section is indicated by the fact that in the chief class, that for one hundred plants, the gold medal presented by the King of the Belgians is offered as the premier award. In a second class for the same number of plants the premier award is an object of art, of considerable value, presented by Comte de Germiny; and in the other classes upwards of twenty gold medals are offered. Turning to the other sections, we find that there are twenty-nine classes for anthuriums and other aroids which enjoy so high a degree of popularity in Belgium and other of the Continental countries; fifty classes for palms, which constitute an important feature of commercial horticulture at Ghent; twenty classes for collections and single specimens of ferns; thirty-six classes for forced shrubs and herbaceous plants, and in these much that is instructive should be found; thirty classes for greenhouse and hardy azaleas, which are grown in such immense numbers in the Belgian nurseries. The more important of the other sections are those devoted to stove plants, cycads and pandanads, greenhouse plants, New Holland plants, alpine and hardy herbaceous plants, bulbous and tuberous plants, trees and shrubs, agaves and yuccas, bouquets and table decorations, and fruits. As will be gathered from the brief enumeration of its more salient features, the exhibition should not only be highly interesting and enormously attractive, but it should afford object lessons of much value to horticulturists. There is usually a goodly muster of Britishers at the Ghent Quinquennial exhibitions, but it must be confessed that those of our compatriots interested in horticulture have not as yet taken full advantage of the opportunities they afford for becoming acquainted with the practice which obtains in Belgium, which has been aptly termed the nation of gardeners. The misapprehension which so generally exists in horticultural circles as to the cost of a visit to the historic city of Ghent has no doubt exercised a deterrent effect upon many, and it is therefore a matter of considerable practical importance that it should be removed. There are several routes between London and Ghent, but those who are desirous of combining economy with comfort may be advised to travel by way of Harwich and Antwerp. The splendid steamers performing the service are unsurpassed in comfort, and the cost of a second-class return ticket from Liverpool Street and other stations on the Great Eastern Railway is about twenty-seven shillings, a sum that may well be described as very small in proportion to the educational value of the visit during the continuance of the exhibition to the city of Ghent, which has long been the chief centre of commercial horticulture in Belgium.

THE POTATO CROP.

THE statistics relating to the yield of potatos in Great Britain in 1897 recently issued by the Board of Agriculture, are at the present time of much interest, for although planting operations are well advanced over the whole of the United Kingdom, considerable breadths of potatos have yet to be planted. As our readers were fully informed in the autumn, the home-grown crop of potatos was last year indifferent in quality and below the average in quantity, and the prices that have ruled throughout the winter have clearly indicated that the deficiency was considerable. From the official returns we now learn that this deficiency amounted to 950,000 tons as compared with the crop lifted in the previous year. This decrease in quantity was due in part to a shrinkage in the acreage, and in part to a lower yield per acre, the area under potatos being 504,914 acres, against 563,741 acres in the preceding year. With the exception of 1894, this is the smallest area that has been devoted to the potato crop during the past thirteen years, and this decrease in the area, coupled with the fact that the yield per acre was the lowest during the period, is sufficient to account for the comparative scarcity of home-grown supplies of potatos. The estimated total produce of potatos in Great Britain last year was 2,608,000 tons as compared with 3,562,000 tons in 1896, or a drop of nearly one-fourth. The average yield per acre is stated to be 5·38 tons for England, 5·10 tons for Wales, and 4·55 tons for Scotland; giving an average for the whole of Great Britain of 5·17 tons, as compared with 6·32 tons in 1896, and a ten years' average of 5·97 tons. From these figures it will be seen that the yield per acre was last year 1·15 tons below that of 1896, and 0·8 tons below the decennial average, The cultivators in Scotland suffered most severely from the unfavourable climatic conditions that obtained during the period over which the growth of the potato extended, and in no year since the produce statistics were first collected has there been so low a yield north of the Tweed. The previous lowest average was in 1890, when the yield was 478 tons per acre, or four and a half cwts. in excess of the average yield obtained last year. On the other hand, the yield per acre of the Welsh crop was considerably above the minimum obtained in the Principality, for in 1890 the average was only 4·43 tons, and in 1888 it was 4·5 tons. The highest recorded average for England is 6·75 tons per acre in 1895; the highest average for Scotland, 6·56 tons per acre in 1887; and the highest average for Wales is 6·96 tons per acre, also in 1887. As the result of the deficiency in last year's crop prices much above the average have ruled in the market, and these have attracted enormous supplies from abroad, the imports for the past three months amounting to 91,973 tons, as compared with 5,500 tons imported in the corresponding period of last year. The Irish crop was even more deficient than that of Great Britain, and it may be assumed that the shrinkage in the Irish supplies has helped materially to enhance prices, for in consequence thereof Ireland has had to buy large quantities of potatos both for eating and planting. It is not surprising that the high level of prices should have induced many cultivators to determine to plant a larger area than usual with potatos; but we trust the general body of growers for market will proceed cautiously in this matter, for an undue extension of the area, which so generally follows a high range of prices, will have the effect of glutting the market and bringing down the prices to so low a point as to leave no margin for profit.

THE AURICULA.

THE first of the special floricultural societies to hold an exhibition in London is that which fosters the cultivation and exhibition of the auricula. While making this fine old-fashioned florists' flower the leading feature, other and varied representatives of the genus are invited, and so many beautiful and some rare species are placed before the public. Were it not for the action of this society many charming forms of the primula would be in some danger of becoming lost to cultivation, because they are by no means commonly grown. The auricula is just now becoming extremely interesting to the florist. It begins to be active in February; it moves forward with stately steps in March; and early in April, though sometimes earlier in time, it commences to unfold its exquisitely beautiful flowers. Meanwhile they have developed their foliage, the leaves gaining in size and vigour daily. Some leaves are green; some have a slight powdering of white meal; others are densely covered with a snowy farina; and the rosette of leaves becomes a striking feature. The green edged varieties—the chief and most valuable type because it has so few high-class representatives—are destitute of meal save that zone of snowy whiteness which surrounds the tube; the grey edges have in some instances mealed foliages of greater or lesser density; the white edges are mainly mealed, the leaves of some very heavily; many of the selfs have leaves largely sprinkled with farina; others have foliage destitute of it. What particular purpose this silvery meal serves in the economy of Nature, is a matter not easy of demonstration. "The flowers," said the Eastern sage, "tell all their secrets to the stars," but their whisperings in many cases fail to reach the ears of men. Meal on the leaves is always in association with farina on the petal edges; though the converse does not always hold good. No two varieties of any one section are exactly alike, and though the range of the section appears somewhat narrowly limited in the schedule of properties laid down by the florist, yet it is possible to raise a large number of seedlings, "every one of which will be found to possess some difference of pattern in its leafy dress, and yet none depart in general fashion from the familiar type." Superficial observers, seeing a collection of auriculas in bloom, are apt to think there is much sameness; but the grower who knows the varieties well, observes in them sharply defined lines of distinction which are as familiar to him as the notes of a music score to an instrumentalist. The greatest diversity is shown in the self class of the florist's auricula, because the range is greater. A deep maroon or velvety black, or a rich blue, provided all other parts of the flower be equally good, usually have the highest value; while in the case of the commoner alpine type, the marginal colour, the exterior band lying beyond the white or golden centre, may and should be shaded, the basal tint shading away to a paler one; the margin of the true self auricula must be unshaded, without the least tendency to pale towards the petal edges or on the surface. This gives a sharp and striking contrast to the zone of white meal surrounding the golden tube in the centre of the corolla. Paler shades of blue, pale wine tints, and anything approaching red, provided it is unshaded, are also acceptable, and even yellow, though a yellow self does not rank high; and yet there is something in the combination of white and gold that fascinates. Green is such an uncommon colour in flowers, that it is, perhaps, not to be wondered at the florists placing the green-edged auricula in the highest rank. Truly has the auricula been termed a "fascinating flower," and it may further be said of it that at all seasons of the year it assumes aspects which are always interesting. The beauty of its plumage of leaves in the height of their development, and in the absence of flowers, has a powerful attraction for the cultivator.

The Royal Caledonian Society is holding its spring show as we go to press, and our Edinburgh correspondent wires that it is a remarkably successful display. Hyacinths, tulips, narcissi in variety, cut roses, roses in pots, and tables of plants are the most prominent features, and attract a large number of visitors. Prizes are offered to the extent of £272, and the society provides music of the highest order, consequently both exhibitors and visitors are numerous.

Starch in Potatos.—Professor E. S. Goff, of the Wisconsin Agricultural College, has been investigating the various conditions affecting the amount of starch in potatos. In the course of these he found that, in different varieties of potatos, when grown under precisely similar conditions, the feeding value may vary to the extent of one half, or even more; while with regard to their percentage of starch, this was also found to vary considerably under the same conditions of cultivation. In the case of different tubers of the same variety, under the same cultural conditions, this variation in the starch content amounted to about a third or more, a difference which did not seem to Professor Goff to be due to heredity. Tubers growing deepest in the soil contained the greatest amount of starch. Mr. Goff also found that potatos which had turned green owing to exposure to sunlight, must not necessarily be considered as containing less starch than others; while he found no relationship to exist between the size of the potatos and the amount of starch they contained. It is, however, well known on this side of the Atlantic that excessively large tubers, produced as the result of a too liberal application of nitrogenous manures, contain a smaller percentage of starch than do those of medium size grown under ordinary conditions. An interesting point elicited was the fact that the flavour of the potato does not depend on its percentage of starch; while the more starch it contains the sooner it cooks, and the more it swells in the process.

The Salt Water Flood in Essex during November last did a vast amount of damage, and unfortunately its influence has not yet been spent. Some fifty thousand acres in this county were flooded during the gale and high tides, some tracts being under water for seven or eight days. Mr. T. S. Dymond, staff lecturer on chemistry to the Technical Education Committee of Essex, states that this land, in its ordinary condition, contains only ·01 per cent. of salt, whereas the flooded land is found by analysis to contain ·20 per cent., equal to two tons an acre in the top six inches of soil. This excess of salt is injurious to vegetation. Peas and tares have suffered severely, wheat has been damaged to a less extent, and where the seed had not germinated does not seem to have been affected. The most serious and more permanent effect, however, is due to the effect of the salt on the earthworms, which after the flood were found strewn upon the surface of the ground, whence they were carried off by the gulls. The use of worms in assisting the drainage and promoting aeration of the soil is universally recognised, and their extermination in the heavy flooded land is therefore a serious matter. The sea salt also, owing to its power of absorbing moisture, renders the soil moist and difficult to work, and also prevents the aeration which is necessary to the roots of the plants, and for promoting fermentation of humus and nitrification. It is believed that many of the Lincoln fens have been rendered unfertile by the destruction of earthworms due to an inundation of salt water early in the century.

Orchid Roots with Fungus.—With reference to the nature of the fungus attacking orchid roots in a damp atmosphere, referred to at the last meeting of R.H.S. Scientific Committee, Dr. W. G. Smith, of the Yorkshire College, Leeds, writes as follows: The orchid aërial roots sent contained a fungus which lives on them, and has killed some already. The absence of any form of reproductive organs renders it impossible to identify the parasite. Other portions of diseased plants (*i.e.*, leaves) would be required to ascertain the true nature of the fungus. The fungus present attacks living cells, consumes the food laid up by the plant, and finally kills the roots. A disease having somewhat the same effects has been found in the vanilla plants of Mauritius.

The San Jose Scale.—The fact that the Canadian legislature has passed a measure prohibiting the importation into the Dominion of fruit trees and vines from the United States indicates that there is considerable apprehension regarding the possibilities for mischief of the San José scale. In Ohio, which is only separated from the fruit-belt of Southern Ontario by Lake Erie, the recent introduction of the scale is traced to two nurseries in New Jersey, the pest having gained access to the latter state through a consignment of plum trees from the San José valley, California. As late as the spring of last year infested stock was in two cases sent into Ohio, through carelessness. In the one case the infested plant was Cotoneaster frigidum, a close ally of a native English shrub—but this was destroyed before being transplanted on extensive private grounds. The other case involved peach trees, which had actually been planted out, but were condemned and destroyed on their being found to be infested with the scale. The extreme minuteness of this insect, its close resemblance to other less harmful species, and the ease with which it conceals itself about the wrinkles of the bark, or under the leaf-buds, all add to the difficulty of its detection, especially when it is present in only small numbers. The Ohio authorities take a view of the general question at issue which shows that they cannot but sympathize with the efforts of people in other countries who adopt or advocate a similar line of action. In a recent bulletin they remark—and it is evident that they speak for the whole of the United States—"It would seem but justice to ourselves, as a nation, that whenever it shall appear that a destructive insect or disease is being introduced into this country, in or upon a particular kind of fruit, brought from some particular locality, and that such insect or disease is likely to cause destruction to the fruits of this country, the Secretary of Agriculture should have authority to protect each and every state from such introductions, to the extent of prohibiting the importation of that particular kind of fruit from localities where such destructive insects or diseases are known to exist." Incidentally it is mentioned that Ohio apples can only gain admission into British Columbia after inspection and being found free from the larvæ of the codlin moth; also, that United States nursery stock is, with that of Canada, prohibited from admission into Cape Colony.

Public Park and Museum at Dulwich.—Mr. F. J. Horniman, M.P., who has done so much already for the South East of London, proposes to house the collections of curios and natural history objects more elaborately than the house they have occupied at Forest Hill (also presented by him) will allow. To this end the Horniman Free Museum is now being built, with galleries, courts, and a large lecture theatre; special provision will be made for zoological and entomological specimens. This museum Mr. Horniman will present to Dulwich and the neighbourhood, together with fifteen acres of surrounding land, which he intends to convert into park and recreation grounds. A library and rooms for scientific clubs will be provided in a mansion already on the estate.

Bees and Fertilisation.—Professor B. Barrows has given an additional reason for not spraying fruit trees while in flower. Wetting the flowers prevents proper pollen distribution, and the use of arsenites injures the delicate floral organs. The learned professor, referring to the importance of bees in fertilising flowers and the recently discovered fact that nearly all varieties of apples, except Baldwin and Greening, are self-sterile, and depend upon other varieties to supply pollen to fertilise their flowers, said the same was true of pears, plums, and grapes. The fruit keeper should therefore avoid spraying his trees with arsenites while in flower, as this will kill the bees which he so much needs, and especially as spraying will be much more effective if done a week later.

Our Native Plants are not nearly so well known as they should be, and those who have a special knowledge of them do not often present the information they possess to an audience in the most acceptable manner. Judging, however, by the reception accorded to Mr. W. W. Pettigrew, head gardener to the Cardiff Corporation, when he lectured upon this interesting subject at the Engineers' Institute, the necessary information with respect to distribution and other matters was given in a most interesting manner. The lecture was illustrated by limelight views, many from photographs taken in Roath Park, Cardiff.

Phosphatic Manures.—An experiment directed to determine whether [illegible] phosphoric acid in mineral phosphates could be rendered available by fermenting the phosphates with farmyard manure, as has been claimed by certain [illegible] has been conducted at the Wisconsin Agricultural College. Finely ground phosphate was mixed with farmyard manure at the rate of fifty pounds of phosphate per ton of farmyard manure. A sample of this weighing eleven pounds was enclosed in a glass jar, the top covered with two thicknesses of canvas, and the jar inserted in the middle of a fermenting manure heap, where it was kept four months. The phosphoric acid soluble in citric acid at the beginning and the end of the experiment was determined. The mixture of farmyard manure and phosphate at the commencement of the experiment contained ·237 per cent. of phosphoric acid [illegible] soluble in citric acid; while after fermentation for four months the [illegible] ·241 per cent., thus showing that little (if any) of the phosphoric acid had been rendered available by the process of fermentation, since the slight [illegible] between these figures might easily be accounted for by slight errors in the [illegible] of analysis.

Ants and Aphis.—A small species of ant, commonly distributed in the Mallee, has a curious habit of keeping in close confinement a rather large mealy aphis, which feeds on the stems of young eucalypts. Writing in the *Victorian Naturalist*, the organ of the Field Naturalists' Club, Mr. J. C. Goudie states that round and over these aphides the ants construct a domed covering of particles of bark, grass, &c., which serves the double purpose of imprisoning the aphides and excluding other ants. Some of these coverings appear to be entirely closed, while others have an opening left in the edge; this doorway is, however, constantly guarded by a pair of ants, which continually move about in the open space, and seem much impressed with the importance of the duty assigned to them. Each enclosure contains generally from three to a dozen aphides, and about the same number of ants. Upon making a breach in some of these structures, for the purpose of observation, he noticed that many of the "live stock" were immediately seized by the ants and forcibly removed to a place of safety. The ant under notice is about a quarter of an inch in length, and is of a uniform dark reddish-brown colour, and forms its ordinary habitation under logs, or in old rotten stumps, and sometimes in the ground. Several other species of ants are very assiduous in their attendance on the various aphides, Tetigonidæ, and coccids, but the above is the only kind noticed that uses such extraordinary means to secure a monopoly of the much-prized "honey-dew."

Sugar and Fruit Cultivation in Jamaica.—According to Sir Henry Blake, late governor of Jamaica, this West Indian colony is not in such a bad way as has been suggested. Before the Chamber of Commerce he observed that in considering the question of Jamaica's condition and possibilities, it must not be forgotten that the circumstances of the island differed from all the other islands of the British West Indies. The island contains 2,692,000 acres, of which about 2,340,000 were cultivated. At present the area under cultivation of the staple crops is 30,000 acres in sugar, 19,000 in bananas, 25,000 in coffee, 11,000 in cocoanuts, and 1,700 in cocoa. The value of the crops last year was £360,000 from sugar, £316,000 from bananas, and £169,000 from oranges. The question arose, Where did Jamaica come in in the general cry of distress? It was not dependent upon any one industry. The sugar production gave the largest ready money return, and was most far-reaching in its effects upon other industries. He looked with apprehension upon the destruction of the sugar industry by the long continued assault of foreign bounties, but he knew that the mere creation of a peasant proprietary would not supply the remedy. In Jamaica there was every anxiety to try and push forward those industries already established, and to establish new ones, but the effect of the West Indian Commission's report had been to obliterate credit, and for the present to paralyse effort. If progress was to be secured in the future it would be necessary for the Imperial Government to give some assistance under safeguarding conditions, enabling local governments to guarantee a certain proportion of capital at low interest where real effort was being made. Sir Henry did not find fault with the recommendations of the West Indian Commission, but he thought Jamaica had a right to ask for the co-operation of the Mother country in establishing a direct line of steamers between that colony and England, as by that means the orange and banana industry of Jamaica would be largely improved, and both these products could be brought to England in proper condition.

Old World Plants and Seeds for America.—Some time ago we stated that Professor N. E. Hansen, Professor of Horticulture at Brookings, South Dakota, had commenced a tour through Eastern Europe and Asia for the purpose of securing seeds and plants likely to be useful in the more arid regions of the United States. The tour was made under the auspices of the U.S. Department of Agriculture, and Professor Hansen, now returned, is preparing his report for the department. He returned with about three car-loads of seeds, and these will be distributed to the various State experiment stations, where the powers of the resulting plants to withstand heat and drought will be carefully observed. The professor made collections in Western China, Siberia, Russian Turkestan, Trans-Caucasia, and Eastern Russia.

Potato Culture Without Water is, according to Mr. T. B. Terry, of Hudson, O., U.S.A., quite possible. He claimed, at a recent meeting of the Michigan Horticultural Society, that, under proper conditions, he could grow a good crop without a drop of rain from planting until harvest. The first requirement is a large amount of humus in the soil. This can be secured by turning under two or three clover sods, and the soil will then be like a sponge to hold rain water and give it up to the crop during the drought. If the soil is of the proper nature and is well supplied with plant food there will be no difficulty about securing a good crop. Mr. Terry grows only medium early sorts that will enable him to sow the land to wheat after taking off the crop. He plants about four inches deep, in drills thirty-two inches apart, and from twelve to twenty inches between the sets, using from six to eight bushels of seed per acre. While this amount of seed will give good results on rich, well-prepared soil, a larger amount will generally be necessary. Before the potatos push through the soil the land should be worked twice with a harrow, to loosen the surface and kill any weeds that may start. When the rows can be seen a cultivator should be used. The teeth may be run four inches deep at this time, but, later on, after the tops are four inches high, this would break many of the roots, and a depth of two inches should be the extreme. At least once a week, and as soon as the ground is in condition, after every rain a shallow cultivation should be given up to the time the vines cover the ground. Much of the cultivation can be done with weeders, at the rate of fifteen acres per day. At first they can be run across the rows, but, later, after taking out some of the teeth, the land should be worked with the rows. This will not only keep the weeds down, but it will act as a mulch and prevent the loss of water by evaporation from the soil. With a soil rich in humus, and a proper amount of plant food, a good crop can be grown, even in a dry season, if careful attention is paid to the stirring of the surface soil.

Ivy Sports.—Dr. Masters exhibited sprays of a peculiar small-leaved dwarf ivy, remarkable for sending up vertical shoots with distichous leaves, though unattached to a wall, at a recent meeting of R.H.S. Scientific Committee. The habit appears to have become fixed, even in free-growing branches. On some shoots, however, the leaves were spirally arranged, as is usual on such branches. It may be observed that the change from the distichous arrangement of the leaves on the horizontal branches of the common laurel to a spiral one, when the boughs grow erect, is common; but it is not a fixed character.

"Blight and Blessing" is the title of the lecture to be given by Mr. F. Enock, F.L.S., at the meeting of the Royal Horticultural Society on Tuesday. We find there is some speculation as to the manner in which a happy union will be effected between such an ill-assorted pair, and also that there is an opinion abroad to the effect that nondescript titles are undesirable in the programme of the society.

Mr. William Iceton, the genial proprietor of the Granard Nurseries, Putney Park Lane, has had to extend his establishment to meet the increasing demand for palms, lily of the valley, liliums, caladiums, table plants, &c. We understand that he has taken the Merton Lodge Estate, situated near West Hammersmith station, and between Ravenscourt Park and Turnham Green stations on the Richmond and Ealing branch of the District and L. and S. W. Railway.

The Lesser Celandine (*Ranunculus Ficaria*) is henceforth to be regarded as a dwarf form of a dimorphic plant, whose dimorphism is of a kind known as gynodiœcism. This, says *Nature*, is Professor F. Delpino's views, the latter contending that the hermaphrodite form is the larger plant, so common on the Riviera, known as Ficaria calthæfolia, and that our Ficaria ranunculoides [?] is the smaller female form of the same species. This theory accounts for the facility with which the Celandine is propagated agamically, and the sterility of its pollen.

Vine Browning. — At the recent meeting of R.H.S. Scientific Committee Mr. Hudson presented a young shoot, the leaves of which were blistered and brown. This is due to the presence of the well-known myxomycetous fungus, Plasmodiophora vitis, which is allied to P. brassicæ, the "slime fungus," which gives rise to club disease, or finger and toe, in cultivated cruciferous plants. The only known remedy is to cut away and burn all affected leaves or shoots. It is described and figured in Viala's "Maladies de la Vigne" (p. 400).

A Horticultural Society for Edmonton was initiated a few days ago at a large meeting presided over by Mr. Councillor Rowe in the absence of Mr. H. B. May. A small membership fee, fortnightly meetings, and lectures upon botany and horticulture were suggested, and the meeting expressed a hope that Mr. H. B. May would act as chairman, and give the society the aid of his long and practical experience.

Evolution of Flowers.—In reference to this interesting question a correspondent writes: The theory of the origin of flowers by the selection of insects is one which has attracted much attention both in scientific circles and from the general public. Set forth by Darwin in the "Origin of Species," it has been largely developed in a series of interesting publications by Sir John Lubbock and Mr. Grant Allen. Some fresh and interesting light has now been thrown on it by a series of experiments recently carried out by Professor Plateau, of the University of Ghent. Professor Plateau has arrived at the conclusion that insects are indifferent to the colours of the flowers they visit, and that they are guided to them in a very subordinate way by sight. The experiments on which the Belgian professor bases his far-reaching conclusions are briefly these. Having covered the brightly-covered flowers of single dahlias in his garden with bits of green leaf, he found that they were still visited by insects. This seemed so much at variance with the generally received view that insects are attracted to flowers chiefly by their colour that Professor Plateau instituted a prolonged series of experiments and observations to put the matter still further to the proof. The result has been to confirm and strengthen the conclusions drawn from the first experiments. Cutting off the brightly-coloured corollas of such flowers as lobelia, evening primrose, foxglove, &c., he found the remaining green parts were still visited. Again there are some brightly-coloured flowers which are seldom, or never, visited by insects, owing to their lack of honey. Notable among these is the scarlet geranium of our garden. But when a little honey was placed on geranium flowers bees came to them at once, those blossoms which had not received honey being passed over. Other conspicuous flowers were tried in a similar way with like results. The experiment of removing the honey-bearing parts of a flower, and leaving the brightly-coloured part which was supposed to be attractive was also tried with the single dahlia. Its inner florets were removed, leaving the conspicuous outer ones, a piece of yellow leaf being placed in the centre. No insects went to these honeyless flowers, but as soon as a drop of nectar was placed on them they visited them freely as before. Again, Professor Plateau made artificial flowers with pieces of green leaf, each furnished with a little honey. These were freely visited by insects; but artificial flowers made of coloured material were neglected even when supplied with honey. In further support of his views Professor Plateau is able to bring forward the following facts as to the habits of insects in visiting flowers: They will pass freely and with apparent indifference from one colour to another of varieties of the same species growing together in our gardens; they visit a great number of green and greenish-coloured flowers; there are many small and inconspicuous flowers which are also freely visited. Such is a brief outline of Professor Plateau's observations and experiments, from which he believes himself justified in drawing the conclusion that sight plays a very subordinate part in attracting insects to flowers. Their bearing on the theory of the insect origin of flowers is obvious.

The Horticultural Club holds its next monthly dinner and conversazione on Tuesday, April 12, at six p.m. The subject for discussion is "Seedling Narcissi," and it will be opened by the Rev. G. Engleheart, one of the most successful raisers of daffodils.

HIPPEASTRUMS AT CHELSEA.

DURING the last week in March and the first two or three weeks in April a very large number of gardeners and employers visit the Royal Exotic Nursery, King's Road, Chelsea, for the express purpose of viewing the collection of hippeastrums or amaryllis in flower at that season. Not only do they come to see the gorgeous display of colour Messrs. J. Veitch and Sons provide, but they come to buy the plants, and the number of buyers is annually increasing, so that quite a hippeastrum cult has now arisen. Indeed, not a few gentlemen vie with each other in the management of the hippeastrum, and exhibit their new purchases or new seedlings to admiring visitors, just as the orchid fancier does his choice odontoglossums. In gardens of any pretensions a batch of hippeastrums is now a necessity for conservatory decoration about Eastertime, and nothing could be finer than the ample, brilliant blooms borne on stately spikes. Formerly the shade of colour known as orange-scarlet predominated, but now, thanks principally to Mr. Hast's untiring efforts, a great variety of colours are represented. Year by year it is not easy to state exactly how much progress has been made among the hippeastrums at Chelsea, but those who have regularly visited the collection for ten or more years find that with the flowering of each new lot of seedlings there is an improvement in shape, variety of colour, purity of the white ground, average number of flowers per spike, strength of foliage, &c.

Fortunately there is no keener critic of the Chelsea hippeastrums than Mr. Heal himself, and none know better than he what result to expect from certain crosses. It is now twenty-three years ago since the first batch of seedling hippeastrums was raised at Chelsea; previous to 1876 seedlings had been raised in a desultory manner, but that year saw their cultivation commenced in earnest. Gradually this new race gained favour, until in 1882 the large span-roofed house, now occupied entirely by hippeastrums, was erected. Since then there has been steady progress, with one or two exceptional bursts ahead, as happened nine or ten years ago, when the enormous-flowered varieties Champion and Optima were produced. The centre bed of the "Amaryllis House" at Chelsea holds 1,100 plants, yielding some 1,500 spikes. During the flowering season there a always from three to five hundred spikes flowering simultaneously, and as each spike carries three or four big flowers the display can be imagined by those who have not seen it. Taking the exhibition as a whole there are two points upon which improvement is very evident this year, viz., the strength of the foliage and the increased diversity of colour. Stout, healthy foliage always enhances the display of this or any other flower, so that improvement in this direction is no small matter.

The older-named varieties that were propagated regularly from offsets are fast disappearing owing to the increased beauty and strength of the seedlings; this, and the fact that such quantities are sold each year, is the reason why by far the largest proportion of the plants are absolutely new and flowering for the first time. Some of the very best of the lighter forms that appear this year are: Padusa, with a white and blush ground colour, crimson feathering, and orange-scarlet apices to the segments; Belus, ivory-white, with dark crimson feathering towards the base of each segment; Feronia, one of the most beautiful, a round flower with prettily reflexed tips to the segments, white throat and margins, scarlet ground colour, and crimson feathering; Cadmea, purest white, with just a few faint rosy-crimson markings; Damalis, creamy-white, with rich scarlet shading; Maceris, blush, with pretty rose veinings and shadings; Harmatus, white, with orange feathering; and Jarbas, a big broad flower with a peculiar faint yellow tint suffusing the creamy-white ground. Whether this will be the forerunner of some yellow hippeastrums time alone will prove. One of the finest forms, and one which flowered in 1897 for the first time, is Mrs. George Gordon; the white is of the purest, and on this are a few flakes of deep crimson. Jobates is a good ivory-white, with remarkable pencilling of crimson on the upper three segments; Pactolus, white and pale orange; Forfarus, ivory-white, crimson, and scarlet; Raphana, white and rosy-scarlet; and Lacenta, white, with deep crimson veinings and orange-scarlet shading, make up a splendid lot of light varieties.

Among darker and more gorgeous varieties Ovid takes a high position by reason of its fine shape and pure soft-scarlet colour, it is a grand variety; Altrata, crimson scarlet with dark veins, is very attractive; Orion shines, as it should do, it is a fine crimson-scarlet form with purest white feathering; Bellanus, rosy-crimson with a suspicion of both salmon and blush, is a most distinct variety; Cyrene is crimson with rose shadings; Bassera is a monster form, orange, with intense orange-scarlet veins; Hygeria is another very distinct form having rosy-crimson flowers, the crimson being deepest at the bases of the segments; this should prove a serviceable parent for future generations. A beautiful hippeastrum is Baroda, its intense crimson flowers are shapely and the colour gleams as if highly polished; Cajesta, orange-scarlet and crimson, reminds one of Champion, but is an improvement as regards colour, especially in the deep and undulating veins; Galenus is clear orange-scarlet; Vagesus is deep crimson and bears several rounded flowers; Harpegus is deep scarlet with crimson shading along the centres of the segments; Ballatus is very handsome, its rich orange-scarlet colour being relieved by the white bases and centres of the segments. Two others must suffice, Zabalus and Damas; the former is rich crimson with a shade of rose suffusing it; Damas has a mixture of crimson and orange-scarlet, these colours intermixing in a most wonderful and indescribable manner, indeed written descriptions inadequately afford any index of the glow and life that a hippeastrum flower possesses—it must be seen to be fully appreciated.

Autumn-sown Onions.—Of these Mr. Beckett, in his excellent paper on Exhibition Onions, states that they never keep for any length of time. Is not that early decaying due more to variety than to any other cause? Probably twenty persons out of every hundred sow in the autumn Tripoli or Italian varieties, partly because these bulb large and early, and partly because the practice of sowing these varieties in the autumn is quite traditional. All of them are notoriously of little value, the white-skinned especially; indeed, these latter begin, as a rule, to decay the moment they are ripe. For that reason how exceedingly wasteful must such bulbs be. What would happen were the harder brown-skinned forms of the round and globe types we now so largely sow in the spring sown in the autumn for the production of fine summer bulbs? Would they decay as early as the soft Tripolis? I think not. In any case, we shall by and by be able to test that point at Chiswick, where there is now growing from an autumn sowing a very large collection of onions, including both Tripoli and Spanish types. As to winter hardiness, the entire batch was hard hit by some of the dense sulphurous fogs of the winter; but the Tripoli were rather worse affected than the Spanish varieties. So much for hardiness. As to keeping, we shall see later on. Also we shall be able to test tendency to bolt to flower or otherwise, on the part of diverse types or stocks. So far as has been practicable, plants from each autumn sowing have been lifted and transplanted into a row close by, whilst a spring sowing of the same variety has also been made.—A. D.

PINCHING CHRYSANTHEMUMS.

THE knowledge that many varieties of chrysanthemums may be induced to give first-rate blooms at a given time through studied manipulation of their shoots, is not unlikely to prove a snare to some whose knowledge and experience as growers is not very great. I am disposed to think this may be especially so with small cultivators who do not usually [illegible] their plants into vigorous growth until late in the spring. Too often, people who meet with failure do not take sufficient pains to determine the exact cause, and on learning that someone who has grown good blooms, adopts a certain practice, or uses a particular manure, they immediately conclude that their remedy is to follow such lines. The great point, however, is to first of all locate exactly the weak spot in our [illegible] management, and then, knowing where we fail, we are much more [illegible] to command success by the avoidance of similar errors.

Since Mr. Shea first recommended "pinching," with a [illegible] "timing" the flower buds, in his very interesting contribution [illegible] chrysanthemum literature, a great deal of conflicting advice has [illegible] given on this subject, and sometimes I am afraid it has not been [illegible] on actual experience. This is especially the case where definite advice is given with regard to novelties which have been grown but one season and in one locality, and though the information may be offered entirely in good faith it does not always prove to be correct. The difference between pinching well grown and early rooted plants, and taking away the points of those which may only just be rooted, or are in a weakly condition, is of serious moment. Growers must allow for this, for to pinch indiscriminately when the plants are not in condition, may mean, if not the ruin of the plant, certainly the prospects of obtaining first-rate blooms. As I pointed out in a recent article, the later propagation of those varieties which give their best blooms from early crowns may probably prove better practice than early rooting followed by pinching, and doubtless such a method, especially for small growers, will be gladly adopted, only it is most important that late cuttings should be firm in growth and strong. Bearing in mind the fact that a week's difference in the "taking" of the flower buds of some varieties, means the difference between a first and a second rate flower, or one which may be too early or too late for a given exhibition, the need of more than one plant of a variety and method of treatment is obvious. It cannot be too strongly urged on amateur growers, who purpose exhibiting their flowers, that a large number of varieties often reduces their chances of success, and that a number of plants of from two to three dozen of the best and most constant, is ample to enable them to enter small classes with better prospects of taking a first place. A few varieties which should be pinched during the first week of April are Golden Gate, R. Dean, Louise, Rose Wynne, Col. Chase, Thérèse Rey (for second crowns), Mons. Gruyer, A. H. Wood, C. W. Richardson, Dorothy Seward, Madame Rozain, Mrs. F. A. Bevan, Mrs. [illegible] Matthew Hodgson, Duchess of Fife, Lord Rosebery, Lyne, jun., [illegible] Stoke Newington, Lady Dorothy, Princess Teck, and the Queens.

Though an occasional sprinkle of clear water over the plants is desirable at this time during bright weather, it is bad practice to give [illegible] and particularly so just as the frames are closed, because we want to [illegible] a soft growth. Most growers are, at some time in their experience, [illegible] or less guilty of encouraging a too rapid and succulent growth [illegible] plants are in frames, and then when the plants are stood out in the [illegible] they suffer proportionately from the cold winds which we so frequently have during May. Such undue hastening of the growth has also the disadvantage of rendering necessary the potting into flowering [illegible] earlier date. If the plants are ready for this during the last week [illegible] it is quite soon enough. The main point now is to give plenty of room between the plants so that the lower parts of the stems have the advantage of sunshine. Remove the lights entirely when the weather is still and mild, and during such weather they should not be closed down at night. Late-rooted cuttings, and amongst these should be a batch of single-flowered sorts, will need potting up soon, as by this time [illegible] should be well rooted. They require to be grown freely, and the [illegible] and attention for these ought to be quite as much considered as for [illegible] main batch, otherwise they may prove disappointing. I do not [illegible] experience is general this season, but of our own stock, so far, we do [illegible] Viviand Morel and Chas. Davis showing flower buds as they [illegible] It is more than probable that this unfortunate peculiarity will assert [illegible] later on, but good strong plants will be less likely to do so, and [illegible] sooner recover a free growth.

It is remarkable what a number of sports have originated from [illegible] Carnot. I have had two more yellow ones sent me for trial [illegible] and even if they do not prove to be of a richer colour than [illegible] sent out they may possess the advantage of a stronger [illegible] we have Mr. Mease's sulphur-coloured sport, and an eminent [illegible] sent for trial what he believes to be a pink one.

W. H. [illegible]

Trent Park Gardens.

Sir Joseph D. Hooker, G.C.S.I., F.R.S., has been [illegible] the Wilde medal by the Manchester Literary and Philosophical [illegible] Wilde lecture was this year delivered by Professor Michael Foster, [illegible] the Physical Basis of Psychical Events."

Discoloured Palm Leaves were submitted to the Scientific [illegible] R.H.S. by Mr. W. A. Holmes, of the Putney Nurseries. [illegible] with numerous translucent spots, and had been taken from [illegible] the Continent. An examination appeared to indicate a previous [illegible] grubs, but none were present, the interior tissue having [illegible] spots; so that the new leaves would probably be quite healthy.

THE WATER GARDEN.

Waterlilies.

THE small water lilies include Nymphæa pygmæa, the smallest, perhaps, of all waterlilies, bearing an abundance of pure white flowers, not much larger than a half-crown piece. Nymphæa pygmæa var. Helvola is only a trifle larger and has pale yellow flowers. Nymphæa odorata minor, a small form of the white American waterlily, has leaves not more than three or four inches across, and small white flowers. Nymphæa Laydekeri rosea is perhaps the gem of, at any rate, the inexpensive kinds, The flowers, which are two or three inches across, are at first pale pink, then crimson, and at last rosy purple; several plants put together into a group have a magnificent effect, undreamt of ten years ago. From this form several hybrids, some of them of exquisite shape and colour, have been raised. Nymphæa Laydekeri fulgens, cup-shaped flowers of a brilliant crimson. Nymphæa L. lilacea, sweet-scented flowers of dark rosy purple colour with yellow stamens. N. L. purpurata is distinguished by large crimson flowers with orange stamens. Nymphæa Laydekeri lucida also has orange stamens and brilliant red flowers. Nymphæa Robinsoni, another deep red form, shaded with yellow, and having orange stamens. It seems to grow freer than the preceding; the leaves are spotted with brown. Nymphæa Seignoureli is straw-coloured, shaded with rosy carmine, stands well out of the water, and has leaves spotted with brown.

The two last-named are among the latest introductions, and are, therefore, among the most expensive.

The large waterlilies are as follows: Nymphæa alba, the common white waterlily; Nuphar luteum, our common yellow waterlily; and the likewise yellow American Nuphar advena, are bold, handsome plants, which may be used with good effect in large waters; but since the introduction of Marliac's exquisite hybrids they are quite surpassed. Some of the most important of these hybrids are: Nymphæa Marliacea albida, a plant of which is shown in the illustration of the rock garden, page 131, February 26, 1898. The dazzling white flowers are nine inches across, rise well out of the water, and are most abundantly produced. Nymphæa M. carnea is equally large, but has flowers of a delicate flesh colour and large handsome leaves; it grows rather rapidly. Nymphæa M. chromatella is another very robust grower, with pale yellow flowers and handsome spotted leaves. Nymphæa M. rosea, also most excellent, with very deep rose-colour flowers. Nymphæa M. ignea, still very rare, has flowers of a deep red colour and orange-red stamens. Nymphæa M. rubra punctata is light rosy purple, spotted with dark red orange stamens. Then there are the forms of Nymphæa odorata, the sweet-scented white American waterlily, which is itself very desirable. The following are among the best: Nymphæa o. rosea has sweet-scented pink flowers of good size; Nymphæa o. rosacea is distinct from the former, has bright rose-coloured flowers with lighter centre, and is fairly robust in growth; Nymphæa o. exquisita has not only red flowers, but dark red leaves as well—the flowers are a deep rosy carmine; Nymphæa o. caroliniana is also most desirable, and has delicate pink flowers with yellow stamens; Nymphæa o. sulphurea is an excellent yellow, deeper than N. M. Chromatella, and of robust growth. At Messrs. Veitch's nurseries in Exeter the varieties just enumerated flourish in pots, which are hung in a large tank by means of bamboo canes thrown across the water. The introduction of the foregoing exquisite nymphæas has marked a new era in "water gardening."

Other Aquatics for Submersion.

Aponogeton distachyon has already been mentioned as requiring to be kept in check, or it will soon monopolise a whole pond, even if this be acres in extent. Stratiotes, the Water Soldier, has most peculiar aloe-like leaves, and is striking on that account. Villarsia Humboldtiana (syn. Linnænthemum) and the yellow-flowering V. nymphæoides are rather fast-spreading dwarf plants, suitable for planting between taller water plants. Nelumbium speciosum is not hardy under ordinary circumstances, but when a small flow of warm water from a factory or other building is obtainable, it will stand even a continental winter, as I have had an opportunity of observing. The large orbicular leaves borne on long stems, and the handsome pink flowers, are most distinct and attractive.

Some few plants need only to be partly submerged, in other words, they are plants for shallow water, for the embellishment of which we are by no means confined to such well-known native plants as the Bulrush (*Typha latifolia*), the Sweetflag (*Acorus Calamus*), or the Arrowleaf (*Sagittaria sagittæfolia*). The Arum Lily does exceedingly well in such shallow water in the south and west of England; even though in severe weather the leaves might be destroyed, they will send up fresh leaves and flowers as soon as the warmer weather sets in. Pontederia cordata is a handsome American aquatic, with spikes of sky-blue flowers. Menyanthes trifoliata, the Buckbean, has beautifully fringed, sweet-scented flowers, but unfortunately somewhat rampant in its growth. Calla palustris, the Bog Arum, looks well in masses, and grows seldom more than nine or ten inches high.

Waterside plants I will notice in a future issue.

Exeter.

F. W. MEYER.

A Central Agricultural Institute is most desirable in the United Kingdom, and the matter is under consideration as a result of a resolution passed at the British Association meeting held last year at Toronto. Agriculture has vastly improved in Canada under the influence of such a central institution, acting as a point of union for the various bodies interested, and by the conduction of original agricultural research. At present the various agricultural societies, associations, clubs, colleges, county councils, &c., of the Kingdom are being invited to express an opinion as to the desirability of a central institute being created by the Government. A committee has been appointed to receive the reports, and act as desirable.

ON LANDSCAPE GARDENING.

GARDENING is an art that can only be efficiently taught by example. Much may be learned by observation, but far more by execution. Professor Bayley Balfour, the Regius Keeper of the Royal Botanic Gardens, Edinburgh, strives to combine both modes of instruction for the young practical students under his care. The young men on his staff work in the gardens during the day, and are provided with lectures and literature in the evening, free of cost. The period of service is three years, during that time a regular course of instruction has to be gone through. At the end of that period, unless the men are retained to fill higher positions in the staff, situations are found for them elsewhere. The public thus secures as gardeners, foresters, or factors, men as competent as a good training can make them. This dual or rather multiple system of teaching has now been in operation for about six years, and is so popular that the number of applicants far exceed those of vacancies. As showing the character of the instruction given and as suggestive hints to horticultural societies, it may be stated that the following courses of lectures have been given this winter. Over twenty on Forestry, by Colonel Bailey, lecturer on Forestry in the University of Edinburgh; three on Nursery Work, by the veteran cultivator, Mr. James Grieve of the Redbraes Nursery, Edinburgh; and a series not yet finished on the Botanical Character of Trees, by Mr. A. D. Richardson, a foreman of the outside department at the Royal Botanic Gardens. In prosecution of the same schemes of instruction, Mr. Henry E. Milner, of London, has given a series of lectures on Landscape Gardening. Three prizes, a first of £3, a second of £2, and a third of £1, are to be awarded to the students who score the highest number of marks in the subsequent examination.

History of Landscape Gardening.

Mr. Milner's first lecture was introductory, and largely historical. He showed how, at the dawn of ancient civilisation, gardens were found in Egypt, China, Babylon, Rome, Greece, &c. In tracing the size and progress of landscape gardening in Britain, Mr. Milner showed the effect of the Italian Renaissance, the Dutch and French styles, on the more sober English style. Coming to the Elizabethan era, he mentioned Hatfield and Holland House as good existing samples of gardens of the period. He also named Thurston, Capability Brown and others, such as Repton, and London, whose works he commended, Marnock, Price, Le Nôtre, and others. Through the many thoughts of these and many more minds, Nature's beauties in scenery, the art that serves to minister to the better feelings, became more definite in its tendency, until the present development of the art of landscape gardening, truthfully and distinctly styled English, has been reached. As Mr. Milner truly shows in his recently published volume on the subject, up to the commencement of the century landscape gardening was mostly the work of architects; and was characterised by formal art features, by intricacy of designs in parts, and by treatment of the ground as a plane surface. Nature it is true is ever at work, and as time passes it clothes even a neglected garden with beauty, and makes an unsightly rubbish heap lovely with her gifts.

Water, by low constant gentle action, or by sweeping force, has been a principal agent in forming the natural surface of the earth. Nature seldom presents a straight line in any of her forms. Lines running in a direction from the line of vision make the space so marked longer; whilst lines running across it make the distance appear less. Falling ground appears shorter, whilst level ground at the base of a hill or rising ground seems longer than it really is. The idea of spaciousness may be artificially promoted by the breaking of boundary lines, and by providing various objects to attract the eye, just outside the direct line of sight; vision invariably travels down hollows or depressions, or through any opening; thus, the idea of distance may be created by directing the vision to distant objects that may be brought into the artists' plan. Trees serve to frame a particular view. The contrast in foliage in trees and shrubs gives variety, and a gradation of colours promotes the idea of distance. Trees should clothe the hill-tops, and slopes in masses of irregular outline. A sky line of trees should not be continuous, but broken. A valley appears deepest when not planted, just as a hill appears higher than it really is by being planted at its summit. Grass clothing the ground surface has an expression of stability; and by its colour it brings out the tint of foliage to which it forms a base and a background. The beauty of water at rest is of universal acceptance. Created water scenery must harmonise with the surrounding land; for fitness to surrounding conditions is itself a measure of beauty. A lake expresses spaciousness, but much on its charm is due to its outline. A river expresses action. Trees on high banks on the margin of water diminish its extent when seen from the opposite side, and may make it dull. An opening in the trees, or an opening in the bank gives a gleam of light, and the length in that direction will appear greater. It is indispensable that portions of the lake and its shores should be hidden from other points on its margin. If the lake be large the end may be turned behind a wood or a hill, or failing such natural objects, by interposition of planting. A vast sheet of water may compel our wonderment, but the picture none the less is circumscribed; if we are able to take cognizance of its features all at once our imagination is confused. In such circumstances the mind seizes with avidity and delight on distant but definite objects, such even as a shore of broken form, or a headland.

Mr. Milner concluded his first lecture with a lucid résumé of his subject matter, claiming for landscape gardening that it was an art which created beautiful compositions upon the surface of the ground. He invited the young men before him to appreciate the greatness of the work before them, and to enter into the spirit of the art. It was the business of the landscape gardener to appreciate the many means whereby Nature expressed her beauty, and to use these means artistically.

Site, Approach, Terrace, Kitchen Garden.

Mr. Milner treated the question of site, in his second lecture, under such sub-headings as sun lines, or aspect in relation to the points of the compass; relation to surrounding objects; natural shelter; convenience of access and occupation; levels of the land and character of the subsoil. As to relation of the house to the sun, throughout the southern and midland counties, S.E. is the best aspect, as thus different rooms would enjoy a more equal distribution of sun than if the front was due south, and the back due north. In more northern counties, more directly southern aspects may be preferred. Having moderated the extremes of heat and cold, sunshine and shadow indoors, Mr. Milner advocates bringing in all possible beauty from surrounding scenery. Distant scenery often lends enchantment to a home view. Views of hills and mountains, lakes and rivers, sea, spreading moors, or mere expanse of field or meadow, if not overdone, are mostly welcome. Shelter is of the utmost importance, and there is nothing so effectual as a wooded hill, this shelter should be provided on the north-eastern, northern, and north-western sides. Were Mr. Milner resident in Edinburgh he would probably include west as also needing protection. Trees or shrubs form the best shelter, as these break and disperse the waves of wind; while solid walls divert them into cutting draughts, or tumble them over in bulk in cold masses.

Considering that homes and gardens are made for daily or hourly use, proximity and facility of access can hardly be too much insisted upon. Only architects, landscape gardeners, and cultivators, can tell of the many homes that have been ruined and gardens spoiled through lack of due attention to the ground levels. Though homes should not be perched up on hills, those are generally the healthiest and the best that are sufficiently elevated. The ground line of the house should always be level. As to the character of soil and sub-soil, there is a general agreement of opinion in favour of gravelly or sandy soil on chalk, sandstone, or other rocks. Mr. Milner, however, would have no fear of building on well-drained clay, were a layer of concrete placed over the clay first. The site of the house, its design, and general arrangement greatly influence the site and character of the gardens. The house should command fine prospects to the south-east and to the south-west; the chief approach or entrance should be on the north-western fall; the offices on the north-eastern side; the stables and kitchen gardens beyond. The pleasure gardens should have an eastern aspect; the south-west looking into into or over the park. The house should also rest upon a base or terrace, which is as needful to give it dignity, as a pedestal is to enhance the artistic merit of a beautiful vase. As to the approach or carriage road, this should always be, or appear to be, the most direct route to the house, and the gradients should not be steeper than one in fourteen feet; should not run paralled with nor be seen from the public road; nor be less than nine feet wide, nor more than twelve feet for a single carriage, or twelve to eighteen feet for carriages passing freely. Mr. Milner gave much useful information as to the position of lodges and entrances from public roads at such points or turns as to make the private approach look the more important road. For straight approaches or avenues, an imposing entrance should be made, and they should also have an imposing finish in a fine mansion. When practicable carriage roads should enter the park on level ground; there should be a considerable level space, called the forecourt, of gravel ranging from thirty, forty, or more square yards, allowed for the arrival, departure, and exercise of horses. The banks of carriage drives, drainage, gulley holes, the levelling of roads, walks, and grounds by spirit levels, and boning rods were then described and illustrated on the black board. Three-inch pipes were considered sufficient for four hundred yards, and four-inch pipes for longer distances on carriage or other roads.

The terrace might be a wide single walk round the house, or a massive built work with copings crowned with vases—the length of the terrace gives importance to a place, its width should be equal to the height of the front of the house. The width of the grass should be twenty feet, that of the walk from nine to twelve feet, and of the grass at the edge of the slope not less than six feet. Terrace slopes should not have a greater depth than five or six feet. Where a greater depth is needed two slopes should be made with a level width between them, if not less than four feet. Where the depth is three feet, the slopes should be two and a half feet, for smaller slopes, such as sunk ponds, two and a half feet will suffice. The steps used in connection with terraces should be as solid and plain as possible. For a two-and-three-quarter feet slope, the tread should be fourteen inches, the rise six inches; for two-and-a-half feet slope the tread should be fifteen inches, with a rise of six inches. Good Portland stone is best, though granite is generally used, as at the Crystal Palace.

The kitchen garden soil and site should be favourable, and the garden should not be further than three to five hundred yards from the house. A hillside sloping towards the south and sheltered by distant plantations from northerly and easterly winds would form an ideal site. From one and a half to two or more acres of good land, two and a half feet deep, well drained and richly manured, should be allowed. The walls on the north side ought to be mostly furnished with glass houses, on the south should be twelve or fourteen feet high, while ten feet is a good height for the east, west, or south walls. Mr. Milner does not approve of broad permanent coping on fruit walls, but described and illustrated a very good temporary coping formed thus: build in the wall and on the coping pieces of one and a quarter inch japanned iron tubing about six feet apart, in which can be placed iron rods projecting in front beyond the wall, having a pin at the outer end. On this support in the spring are placed light twelve-inch boards, which are retained there as long as necessary. Netting can also be suspended from these rods to protect the fruit against frost, birds, &c.

Drainage.

To show the necessity of drainage a few general principles as to the qualities and quantity of water were referred to. One inch of rainfall per acre gives one hundred and one tons, or 3,630 cubic feet of water, which would fill a tank thirty feet by twelve feet by ten feet, yielding two and a half cubic feet, or fifteen and three-quarter gallons per minute if the same fall continue twenty-four hours. The annual rainfall of London averages twenty-six inches, and it is reckoned that at least two-fifths of it percolates through the soil, the other being lifted by evaporation. As water is heaviest at a temperature of forty degrees it follows that the warm rainwater and air cannot displace the colder already in possession, hence the necessity of removing the cold stagnant water by means of drainage. Raindrops are also highly oxygenated, and their passage through the soil by drainage brings this essential aid to vigorous growth within easy reach of the roots of plants. Streams of warm air also follow on the back of descending water, and this also is charged with many ingredients for the support of plant life.

The depth and fall of drains are of great importance. In clay soils, three feet deep and sixteen feet apart; in light soils at intervals of forty feet and four feet deep. In non-porous soils the drains should be filled to within six inches of the surface with porous material. The fall of main outfall drains should be 1 in 500, or 10 feet 6 inches per mile. In collecting drains the minimum fall should be 1 in 250, or 21 feet per mile. Facts, figures, and formulas were also shown on the blackboard for measuring the discharge of water through pipes or open channels. The following table of water discharged through pipes of different diameters can hardly fail to be generally useful, as well as to give one a vivid idea of the vital importance of the drainage of land: A 1 in. pipe discharges 3 gallons per minute; a 2 in. 18 gallons; a 3 in. 50 gallons; a 4 in. 112 gallons; a 6 in. 283 gallons; a 9 in. 778 gallons; a 12 in. 1,600 gallons; an 18 in. 4,400 gallons. As to the size of drains in main walks, 3 in. pipes will suffice for 100 yards; if much over this 4 in. had better be used. The centre roads or walks, connected with gulleys, or the outlet kept well above the level of the discharge, is the safest position for main drains. Sites or characters of soil powerfully modify drainage, such soils as clay, sand, loams, humus, calcareous, and peaty soils, requiring distinct treatment.

Water in Garden Scenery.

Coming to water as an essential element of landscape, Mr. Milner had much to say of its beauty and of the best mode of heightening its effects in landscape. How true it is that each river has an individuality, a fascination of its own. When we wander from lake or river, we soon return to them again as to old friends. Water adapts itself to and should ever be true to its own environments. We should imitate the beauty of Nature's operations, but not distort her efforts. The placid lake has its own special beauty on low-lying land, the shining river strongly sweeping through fat meadows, the rushing stream leaping over the rocky cascade. The landscape gardener's treatment of the lake and stream are different. Very much of the beauty of the lake flows from its outline, and its charm largely consists in the variety of its creeks, bays and promontories. No regular figure, not even a semi-circle, should be used. The prevailing line must be concave. Portions of the lake and its shore must be hidden from the spectator from other points on the margin. Large trees on the opposite shore or the end of a lake lessen by more than their height the apparent extent of water. Lakes surrounded by trees also give a gloomy impression. Belts of wood or banks of earth, as already intimated, should be broken. The main views from the house should be directed into the bays, as here is the widest expanse of water. As the form suggests, the idea should be fostered that these were formed by Nature. In the process of excavating the lake the promontories or projecting points should be raised above the surrounding level. Islands should never be placed in the centre of the lake nor nearer the shore than sixteen feet. Should these be connected by a bridge with the mainland, it should span the narrowest point and at right angles with the shore.

The depth of lakes should not be less than three feet. This will be obvious when it is borne in mind that the evaporation in a dry season may exceed the rainfall by some thirty inches in the year. Mr Milner proceeded to give careful and elaborate instructions as to the excavation and rendering waterproof lakes, ponds, or other artificial pieces of water. Even on strong clays there are generally at least some six inches of surface soil more or less porous, while on more porous lands the entire lake bottom and sides must be made water-holding either with concrete or puddled clay. Concrete is perhaps best on sandy or gravelly soils on a solid foundation. It should be made of one part of hydraulic lime, or one part of Portland cement and six parts of broken stone or sand. This, Mr. Milner showed by a section, should be laid twelve inches thick on the bottom and eighteen inches at the side, this being floated home with one inch of pure cement. There are two ways of puddling lakes, ponds, &c., into water holding. One is to use the clay in a similar way as cement. After cutting, beating, maturing, or forcing it into plasticity through a mortar mill, then stamp or ram in the clay a foot thick over the bottom and eighteen inches up the sides like cement. In many cases there may be a retentive base for the water in the natural soil, and the water leaks through the sides or ends. In such cases it is cheapest to dig out a space for a puddle gutter down to the water-holding space. This trench should increase in width as it descends, and the surface should rise a part above the water level. It should not anywhere be less than eighteen inches in thickness.

Fountains.

Of fountains, of which illustrations were given, interesting particulars as to height of basins, jets, discharge of water, were given. Many garden fountains do not rise higher than a foot above the ground; some, however, rise to a height of three feet. Mr. Milner quoted those at the palace of Count Festetics, at Thesthelly, in Hungary. The fountain basins are raised three feet above the general level, and from each basin radiate walks and similar stone basins to contain plants; the effect is said to be good. The height of a jet of water is less than the head owing to the resistance of the air, the friction through the pipes, and other causes. Thus with a head of eighty feet and a jet of one inch diameter there will be a loss of ten feet, reducing the jet to seventy feet; but with quarter-inch jet the loss would be about forty feet, or half the height of the head. The form of the nozzle and size of the discharge pipe likewise very largely control the distribution of water. Thus, with a head of eighty feet and quarter-inch jet the discharge is 8·58 gallons per minute, with half-inch 34·3, and with one-inch jet 137 gallons per minute.

Bridges.

These were very fully treated, especially in their carrying capacity and breaking powers. Elaborate figures were given as to best material, sizes, &c., which render breakdowns impossible. The breaking power of all bridges should always be far higher than their carrying capacity. Turning from the engineering aspect, and the landscape gardening effect of bridges, it was shown how they should always be made to harmonise with their position. If placed on a straight walk it should be massive and partake of an architectural character; if in a winding walk or crossing a running stream, of a rustic or picturesque character. For such purpose a peeled oak, larch or fir can be used. Boat-houses, summer-houses, arbours and seats often add convenience and beauty in such connections.

D. T. F.

Harrow Weald, Middlesex, is being brought under proper government by the Board of Agriculture. Conservators will be appointed whose duty it will be to preserve the turf, shrubs, trees, plants, and grass, to execute such works of drainage, levelling, fencing, planting, &c., as may be necessary for the protection and improvement of the common, and to set apart a portion or portions for games. They will be empowered to frame and enforce bye-laws for the preservation of order and the prevention of nuisances, the removal of gamblers, card-sharpers, gipsies, &c., and generally for the prevention or restraint of any act or thing tending to the injury or disfigurement of the common, or to interference with the use thereof by the public for purposes of exercise and recreation.

French Beans.—There is no worse month than March for the culture of French beans. There are extremes of heat by day and of cold by night, and this is the very reverse of what the crop likes. Then we have the very cold, cutting winds to deal with. Lastly, there is the question of water, which should always be warm. In sowing I find the general error is to sow too deep; one inch or one and a half inches below the surface is ample. A spare box of seed should be sown at the same date—or a few days later than the crop—so that any blanks can be filled up. Water the seed box carefully, so that in planting there will be [illegible] flagging. As a rule, I have found transplanted beans about equal to the [illegible] for crop, though they may be more dwarf. Where there is space for sowing [illegible] end of March, a good and certain crop is readily obtained, and if the [illegible] are low the crop is heavy. Clean foliage is an absolute necessity, not only for the beans themselves, but also for the other inmates of the house. Sir Joseph [illegible] is the best variety with me, notwithstanding the many sorts I have tried, [illegible] and old. While they enjoy fairly rich soil and do well up to flowering time [illegible] almost any material, after then it is time to feed them. Soot in any [illegible] desirable and safe food, and this can be given either in liquid or solid form. [illegible] pailfull of cow manure soaked over night and diluted and strained next day will be found useful, but use no cold water.—*Stephen Castle, F.R.H.S.,* [illegible] *Vineries, Notts.*

THE BEST GUIDE to the garden for the whole year is the "Gardening [illegible] containing practical articles on the cultivation of Flowers, Fruit, Vegetables, [illegible] "Gardeners Magazine" Office, 4, Ave Maria Lane, London.—[ADVT.]

THE GHENT SCHOOL OF HORTICULTURE.

Situated on rising ground in a pleasant suburb of Ghent is the celebrated School of Horticulture and Agriculture of the State of Ghent. Not only is it pleasantly situated, but it is admirably managed, under the able directorship of M. Emile Rodigas, whose name is a household word in the horticultural community of Belgium. The school is aided by State and Government, and is under the special care of the Minister for Agriculture. The various courses of lectures given and classes held are such as, together with the practical work that has to be performed in the extensive gardens and nursery, would give to a young and aspiring horticulturist a magnificent start in his profession. A complete course of instruction occupies three years, but the authorities do not confine their attention entirely to the resident students. When visiting the school about midday on one occasion we remarked to M. Rodigas that not by any means were all the students youths and young men. The genial director pointed out that the middle-aged students did not work in the school grounds, but were from surrounding gardens and nurseries—men who were anxious to advance themselves, and to that end gave up half their dinner hour to attend the lectures open to them at the State school.

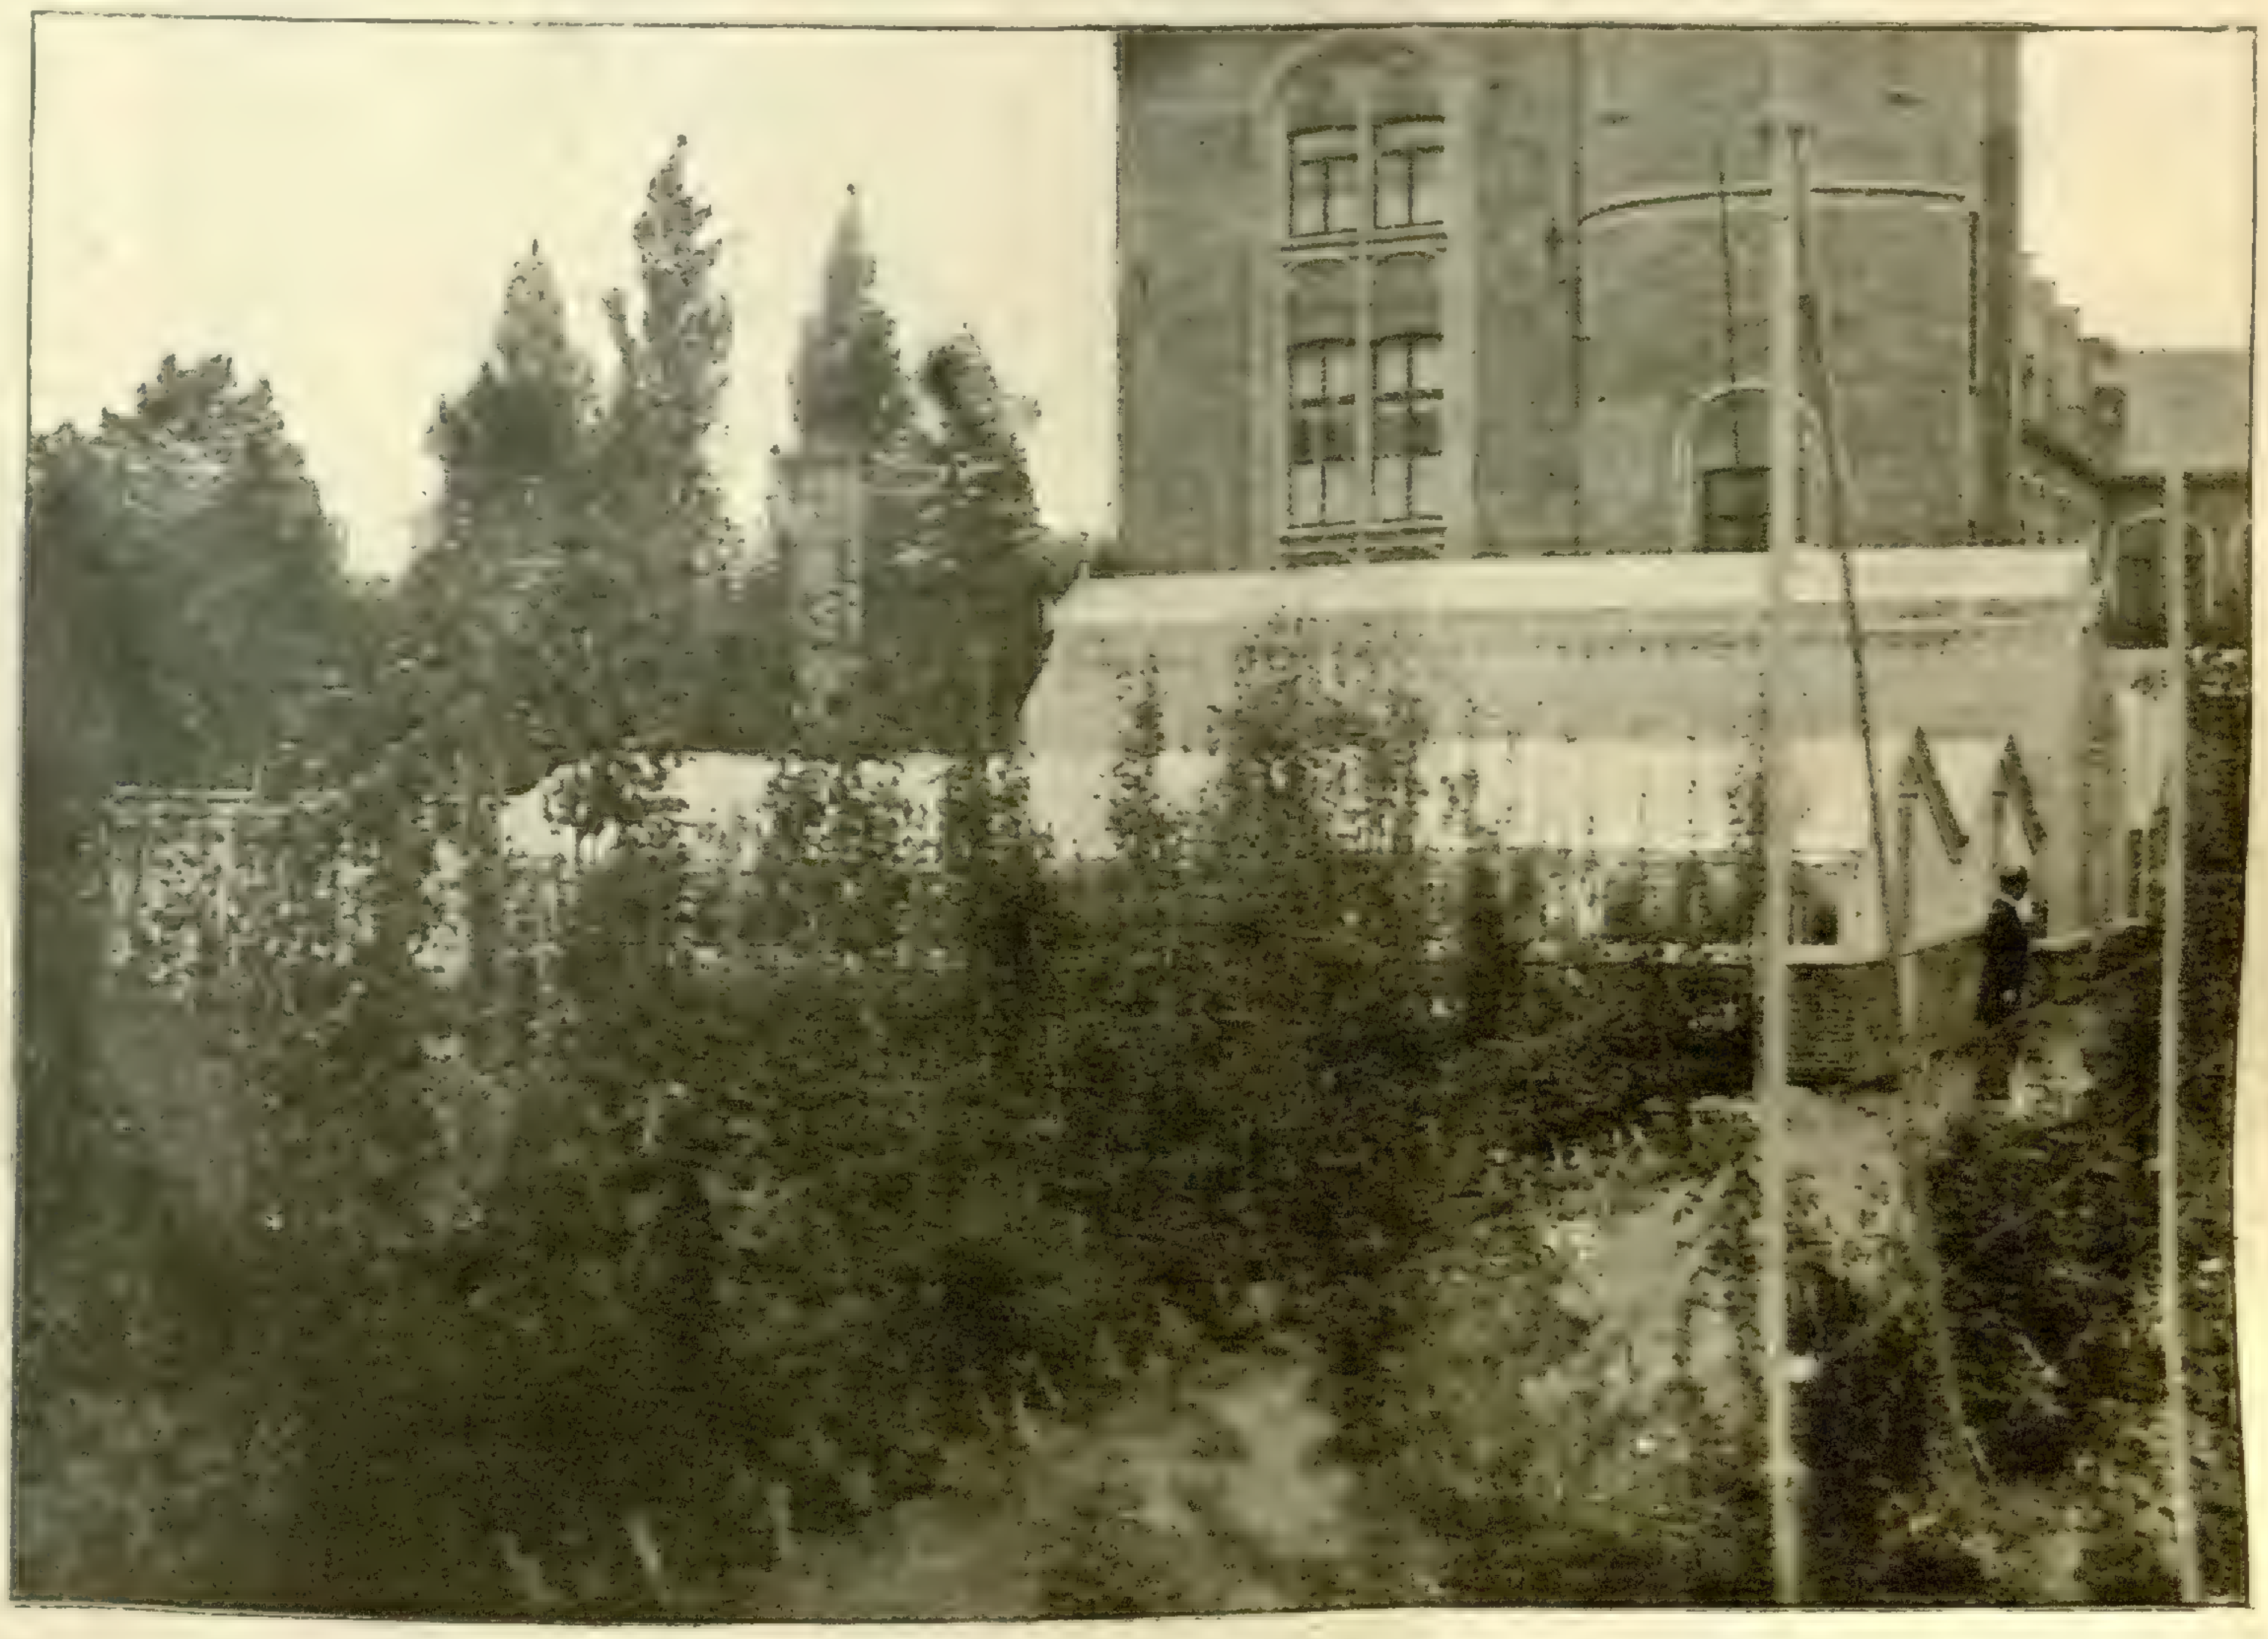
M. Emile Rodigas,
Director of the Ghent School of Horticulture.

A history of this famous school would prove interesting reading, for in its earlier days it had to contend with some difficulties. It was instituted in 1849, for on April 24 of that year it was agreed to provide suitable instruction for twenty-four students desirous of studying horticulture and its allied sciences. The scheme was approved by the Government on April 30, when presented by M. C. Rogier and M. Louis Van Houtte, and the Minister of the Interior was instructed to see it executed. In later years the school has come under the Department of Agriculture. Horticulture has long been one of the leading Belgian industries, and nothing has done more for its advancement during almost half-a-century than the Ghent School. Belgium has much to thank MM. Rogier and Van Houtte for, because it was owing to their untiring efforts that the institution obtained a fair start. The latter, one of the most eminent and broad-minded horticulturists of his day, was mainly instrumental in securing Dr. Planchon as director of the school. Not only was Dr. Planchon a brilliant scientist, but he possessed remarkable administrative ability, and this is evidenced by the code of regulations he drew up, and the courses of instruction he instituted. Both these have been modified to suit the needs of the times, but they have served as a base for codes drawn up for the principal horticultural schools of later times. It was ever the aim of the authorities to secure the best of instruction, consequently there was a succession of illustrious professors, and a sure foundation of theoretical and practical knowledge was laid in the minds of the students.

Another director of note was M. Jean Jacques Kickx, who, after a brilliant career, died on March 27, 1887. Mons. Kickx was succeeded in the conduct of the institution by the present director, M. Emile Rodigas, whose portrait is published in the present issue. M. Rodigas entered the Ghent School of Horticulture as one of the professors in 1860, so that his connection with the establishment has lasted thirty-eight years. M. Rodigas is beloved by all who have been students, or who have in any way been associated with him, and on at least two occasions there have been great reunions and demonstrations that must have delighted him. These were in May, 1885, when he had been professor for twenty-five years; and in 1895, at the conclusion of thirty-five years' service. Besides being an administrator and professor M. Rodigas is an ardent lover of hardy plants, taking an especial interest in alpines, and finding the greatest pleasure in conversing about them. To the stranger, as the student, M. le Directeur is equally pleasant, and those who have once visited him at the school never forget to make a call when in its neighbourhood. M. Rodigas will have plenty of visitors during the forthcoming Ghent Quinquennial Show.

To afford practical instruction for a large number of students, and in all the branches of horticulture and agriculture, a large area of land is necessary, so we find the State school of Ghent surrounded by about eighty-four acres. This gives some variety in soils and aspects, and room for plantations of forest trees, nurseries, rose garden, pinetum, glass houses, &c., &c. The establishment is divided into four divisions, the first being the school proper, part of which is shown in one of the illustrations; this includes the large lecture rooms for public conferences, the laboratory, school offices, and residential quarters. The second division comprises the extensive glass department, and the large fruit garden in which it is situated. The houses are devoted to fruit and plant culture, vines, new Holland and Cape plants, and orchids are especially well represented. The third division practically covers all the plants out of doors excepting fruits ; vegetables are largely grown and varieties tested; annuals find favour, and large breadths are grown to teach the business of seed harvesting later; herbaceous and alpine plants are freely cultivated, especially such as are serviceable for horticultural purposes, as apart from purely scientific interest. One of the accompanying illustrations shows a corner in the alpine garden, while another gives the principal block of glasshouses. Division four is a comparatively new feature, and is not found close to the school, but a few minutes from it. Here are grown collections of conifers, ornamental trees and shrubs, and here also are the fruit tree and other nurseries. A businesslike method obtains everywhere, and there is evidence that the students take a keen interest in their work as well as in their studies, and hitherto such evidence has not been contradicted by the results obtained by those who have passed through the prescribed course of instruction with credit. As showing the capacity of the establishment, it may be noted in connection with the fourth illustration that the laboratory allows of thirty students practising at one time.

In conclusion, it will be of interest to readers to have some idea of the course of study M. Rodigas has found to be productive of the best results when combined with practical horticultural and agricultural exercises. During the first year the student is taught the Flemish, French, and English languages, mathematics, freehand and mode drawing, and physical geography as general subjects. In natural science he studies botany and physiology, physics, chemistry, and geology, in addition to applied chemistry, agronomy, principles of agriculture and horticulture, aboriculture, and kitchen gardening. Anatomy, designing, and planning are also added. During the second year all the foregoing subjects are continued in an advanced stage, while zoology and entomology, so far as these affect the student, are studied together with landscape gardening, construction of glass houses, and garden archi-



GHENT SCHOOL OF HORTICULTURE.

tecture. The third year finds the student progressing in his studies, and frequent revision and examinations fix them upon his mind. He is now able to appreciate the widespreading influence of the profession he has entered, and so, ere quitting the school, he is instructed in all the legislation affecting the industry, and allied subjects, such as beekeeping and dairying, are dealt with. His education assumes a more commercial aspect, and he may study special subjects, such as sugar extraction, distilling, brewing, wine making, &c. The necessity of intensive culture is made apparent, as also is that of economical methods of procedure, the necessity of insurance, and values of land, and capital and labour. Altogether, a smart young man entering the Ghent School of Horticulture has an opportunity during his three years' course of obtaining such general, practical, and theoretical knowledge as many a Briton would be glad to possess, but which his Government does not provide.

THE PLANTING OF GLADIOLI.

WHATEVER may be the difference of opinion as regards planting gladioli, whether it should be done in March or April, no one will hesitate to plant during this fine weather. I do not think that any fresh light has been thrown upon the many questions which have perplexed growers of this beautiful autumnal flower, and therefore the old ways had better be adhered to. There are some things which I have always advocated in the spring work connected with this flower; and there is one point on which nothing need be said, namely, the choosing of a favourable day, and the non-planting when the ground is at all wet. I have also advocated for many years the cutting of the large corms in two where there is a sufficiently pronounced eye to be seen; it is better, I think, for the shoots of two spikes of the same bulbs are sure, more or less, to interfere with one another, and where the variety is a scarce one you by this means double your stock. I know some object to this plan, but I have never heard a good reason against it, and as far as my own experience goes, the corms produced by those thus treated are larger than where they have been planted whole. Another point is that it is desirable to give the plants plenty of room, not so much for the sake of the nourishment supplied as for easier manipulation afterwards. I have seen them grown very closely together, not more than four or five inches apart, and apparently without any loss of vigour, but any one who has grown them knows that the roots do not at all spread but go straight down. I have known them planted a foot apart, but I do not think this necessary; eight inches is far enough. As I grow nearly all named varieties, I am particular about their being carefully labelled; I use the labels about a foot long, and, moreover, write down the names in a book, so if any label is displaced I can immediately rectify it. In planting I bore a drill about five inches deep, and put a little road grit or powdered charcoal at the bottom, so that when the corm is planted there are about four inches of soil from it to the surface; when the whole row is planted it is covered in and the next row proceeded with; from this time forward until the shoots are about a foot in height they will require but little attention save weeding. In all these directions I have simply in view the varieties of the gandavensis section; I have grown some of the Lemoinei and nanceianus groups, and these being robust growers may be left in the ground from year to year, giving the clumps a slight covering of ashes during the winter. These do not to my mind equal those of the gandavensis section, either in length of spike or colouring; what may yet be evolved from them it is, with the experience of the gandavensis section before one, difficult to tell; I remember when we were contented with spikes of four or five blooms opened at once, whereas now we have from sixteen to twenty expanded at once, these being twice or three times the size of the old varieries.

When writing of the gladiolus there is always one painful fact to be noticed, namely, the decay of the bulbs, and the past season has been no exception to the general rule in that respect. When I lifted my corms in the autumn I thought I had never had a healthier looking lot; the skin had that soft silky appearance which usually portends a healthy bulb underneath, but, alas! for the vanity of human wishes. I always make a point of stripping off the outer skin before planting, and in very many instances a mass of corruption underneath manifested itself, caused by a fungoid growth which completely destroyed the vitality of the bulb. In all such cases the question arises: is this the cause of the decay or the result of it? Opinions have differed and will differ, but whatever the opinion the melancholy result is the same. I have seen the disease in bulbs imported from France as well as in home saved ones; it is of course very aggravating when you have paid half a guinea for a corm, and when you have seen it start vigorously into growth to find it all at once drooping its head and refusing to expand its flowers. Having grown gladioli close upon forty years, I can testify that I am as much at sea now as I was at the commencement of my culture with regard to the disease. I have seen a dozen bulbs planted of one variety, when perhaps only two of them have succumbed, and I have in other seasons lost nearly my whole collection. As my garden contains a good deal of old manure, it may be, although I change position every year, that this is injurious to the corms; this is, I know, the opinion of my friend Mr. Burrell, at Cambridge, but I have never known anyone who has grown gladioli who has not had to deplore losses. It is not everyone that has such splendid soil as Mr. Burrell has in which he can grow roses and gladioli so well; there is, however, this comfort, that anyone who wishes to continue their growth has only to save the small bulbs, or spawn, as we call it, which in some varieties is very abundantly produced, and seems to be in no way affected by the decay of the parent bulb.

GLASS STRUCTURES AND FRUIT GARDEN, GHENT SCHOOL OF HORTICULTURE.

It may be asked, perhaps, what varieties are to be recommended. I would suggest that the following varieties be obtained, they can be had for a few pence each: Africaine, very dark chocolate brown; Amalstree, pure white with violet blotch; Amitié, pale creamy rose; Archduchess Maria Christine, white tinted and flaked with carmine; Atlas, pale porcelain; Baroness Burdett Coutts, lilac, tinted with rose and purple; Caméléon, slaty lilac, striped with white; Caprice, creamy white, shaded carmine; Carnation, pale flesh, tinted with carmine; Cervantes, bright rose; Conquérant, dark purplish carmine; Corinne, carmine, with white stripes; Dalila, bright rose, striped with white; Dr. Bailly, bright scarlet; Enchanteresse, pale rosy white, striped with violet, large and fine; Eugéne Souchet, bright rose, with large white stripes; Flamboyant, bright scarlet crimson; Formosa, pale satin rose, large and fine spike; Glaive de Feu, salmon rose; Grand Rouge, scarlet crimson; Horace Vernet, purple red, striped with white; Le Vésuve, fiery red; Matador, bright cherry red, very late; Meyerbeer, bright vermilion; Néréide, pale lilac rose; Ondine, white, tinted with lilac; Orphée, cherry rose; Pasteur Ovide, purplish carmine, striped pure white; Pactolus, yellow; Pyramide, clear delicate rose, slightly tinted orange; Pollux, carmine; Pyramide, clear delicate orange rose; Rayon d'Or, yellow; Rossini, dark purplish red; Sceptre de Flore, rose colour; Shakespeare, white, very early flower; Tour du Monde, dark cherry, shaded lilac.

There are many newer varieties of much merit, but I think those named above are sufficiently varied, and will not fail to give satisfaction to the grower.

H. H. D'.

THE FUCHSIAS OF FORTUNATUS.

I TEMPTED Fortunatus and he fell.

It was the old story—a quiet worker pursuing his useful way in a country place, happily ignorant of the turmoil of the world, until the word "exhibition" was mentioned, then a transformation into the eager, restless, combative being whose heart is no longer in the garden, but in the money-bags of committees.

LABORATORY, GHENT SCHOOL OF HORTICULTURE.

I had done an evil thing unwittingly in recommending Fortunatus to try his strength at the shows. He was so striking an example of practical genius unexploited, and appeared, in his staid, reflective way, so completely under self-control, that a prospect of harm arising from a suggestion that he should make a bid or reputation seemed remote. But a few victories made the error plain.

A CORNER IN ALPINE GARDEN, GHENT SCHOOL OF HORTICULTURE.

Fortunatus secured his first triumphs with vegetables, but I, who had been trained where big specimens grew, perceived that his real strength was as a plantsman, and threw out a suggestion that he should concentrate his efforts on pot stuff. Willingly assenting, he gathered round him his rough material and read up for hints from the noisy, "practical" ones who clamour to advise. Now, when you have been where the big plants are, you can claim to have learned one great initial lesson, namely, that it is not the clamorous ones who win the prizes, although, by dint of the noise they make, they get put on committees and wear ribbons and rosettes at the principal shows. As great nations are governed by secret cabinets, so the work of nations is done by the quiet thinkers. Therefore when this eager young gardener, ambitious and aspiring, went to the oracles I smiled, and only when he came back empty did I tell him what the Old Chief taught me—the chief who won countless prizes by his steady but wordless pertinacity.

It was with fuchsias that Fortunatus most yearned to shine. He did them well, but not so well as to satisfy him after he had seen the photographs I showed him of the Old Chief's plants. The prints were yellowing with age (which, being photographically interpreted, means with the imperfect oxidation of the silver salts), but they showed plants of noble and majestic proportions, by judgment seven to eight feet high, absolutely symmetrical, and bloomed from base to summit. Very likely some modern gardeners would have sneered at them, for the simple but sufficient reason that they could not produce the like. To sneer at a plant is as easy as a sneer at a man, and each is the usually cheap refuge of baffled impotence.

Fortunatus envied, and, recalling one maxim of the Old Chief for the young fuchsia, I threw out a suggestion of phosphates. The anxious cultivater stared. Phosphates for fuchsias! He had never read that, and, rather alarmed at the unknown thing, raised seven or eight objections, but the seven or eight-feet fuchsias in the photograph silenced them all. The mixture was prepared as follows: From the loam store was drawn three parts, chopped up, not sifted. The selected portions were full of fertile fibre, well-decayed and fat with sustenance. From the spent mushroom bed was taken one part—dry, friable, crumbly stuff, as full of nutriment as the loam. This was lightly rubbed through an inch-meshed sieve, but not powdered. From the leaf-mould heap was drawn one part more, and it was treated exactly the same as the mushroom manure. To a heaped barrowload of these three ingredients were added one quart of wood ashes and one quart of superphosphate. Fortunatus began to get more comfortable as the heap progressed, for he liked the look of it; in fact, the gusto with which he set about the task of mixing was pleasant to witness. By the time he had done he had more than a glimmering of the why and wherefore of it all, for, as he administered the finishing touch, he remarked quietly, "There's another ingredient in this here mixture, and that's brains."

We won't stay to argue whether it was the loam, or the manure, or the leaf mould, or the wood ash, or the superphosphate, or the brains which suited the fuchsias; but something did, for they throve amazingly. Such mats of fibre did they push into the sweet and firmly-compressed soil that they were asking for a larger pot and yet another, before the neighbouring plants had made a fair start. The delighted grower watched the extension of healthy, succulent shoots—whole sheaves of them—with a beaming eye. It need hardly be said that this exuberance received watchful attention; that it was judiciously restrained and controlled, never being permitted to develop into rampant barrenness. In the course of one short season, the fuchsias, very moderate material when first taken in hand, were stately pyramids nearly six feet from the base of the pot and full of flowering wood. It was evident that in the heavy task before them a little extra help was needed. Fortunatus obviously yearned to hear the word "phosphates" once again. He had taken a fancy to it. It represented a mysterious thing that fuchsia growers had unaccountably overlooked, and was at the bottom, he believed, of all his success. When, therefore, I said "nitrates" instead of "phosphates" he was crestfallen. But I explained that the nitrates in the fibre were much more likely to be exhausted than the rich store of phosphates, and prescribed a top-dressing of finer mould with a small admixture of powdered fowl manure; supplemented by applications, made twice a week, of a nitrate of soda solution, half-an-ounce to the gallon of water.

The flowering of the plants was the event of the season. They bloomed magnificently. People seeing the noble pillars of lustrous grace asked each other if the modern objection to large things because they are large and irrespective of their intrinsic beauty, is well founded—whether, in short, we are not making too many concessions to the ladylike "sweet and small" school. Be that as it may, the plants came triumphantly through the exhibition ordeal. The name under which praise was given to them by the reporters of the gardening press was not that at the head of this article, but in every other respect each reference and statement is perfectly accurate. I say this to answer a possible criticism that because the form of the present communication is not quite similar to the orthodox style it must necessarily be more than half fiction—a criticism not the less unlikely because so very foolish.

But the history of Fortunatus and his fuchsias is not quite told. When the next season came and with it the time to survey the framework of the dormant plants, hope sprang lightly in the exhibitor's breast. Could he but clothe these skeletons as they had been clothed the year before, they would, with the natural development and expansion of greater maturity, be such plants as the world never saw. Unhappily, however, the phosphates and nitrates still haunted him. He relegated the loam and the leaf-mould, and the manure, and the wood ash (and with them the brains), to a subordinate position, and crammed the phosphates and the nitrates in. But although the head loomed big the roots dwindled, and at a crucial moment the magnificent superstructure collapsed.

It may help the ingenious reader to take the moral which I had in mind in the beginning if I hint that public applause and sensational curiosity no more suffice to make strong National societies than phosphates and nitrates do plants, but that a loamy reserve and fertile working balance mingled with brains, give a sure foundation. Beyond this I can only say that if the moral does not show itself, perhaps the hint given with regard to the compost may be a justification for what is herewith written. After all, a seven-foot fuchsia is as good as an attenuated moral, so if the latter remains obscure try the soil mixture and see if the brains are there.

W. PEA.

Slugs and Snails are, like the poor, always with us, and are so destructive, more particularly in gardens of small size, that any new suggestions for their destruction are deserving of attention. A method of destroying these pests, which are especially active this season, is described in the *Journal de l'Agriculture*. The destructive molluscs seek refuge in large numbers in hedges and shrubs, and the plan is to spray these, especially near the ground, and before the appearance of the leaves of deciduous shrubs, with a weak solution of sulphate of copper (blue vitriol, or bluestone), the strength not exceeding four per cent. Morning or evening is the best time for spraying, and the snails will be speedily killed. After the foliage has appeared sulphate of copper by itself becomes injurious, but *bouillie bordelaise* (lime and sulphate of copper solution) or, better still, *bouillie bourguignonne* (sulphate of copper and carbonate of soda dissolved in equal parts) should be sprayed vigorously into the midst of the bushes. For ivy-covered walls it will suffice to sprinkle sulphate of copper solution along the bottom of the walls only.

AN EVENING DOSE.

RASPBERRY CULTURE.

I DO not so much mind "Lux's" weighty condemnation of my notes on "Modern Raspberry Culture," but I certainly have good cause to reflect upon the note of warning as to Peter's non-approval of my methods of culture. As this seemed a case of two to one I began to think either "Lux" or Peter, or both, were affected by the cold unseasonable weather coming after the genial spring experienced before the advent of the Spring Number of the GARDENERS' MAGAZINE, or that their raspberries were touched by frost, or, at any rate, I had touched a tender spot. I immensely enjoy reading "Lux's" notes, but am greatly troubled when they relate to myself and Peter joins the fray.

"Lux" says I deprecate trenching, and that on such light soils trenching is most needed. In spite of Peter, however, I must remind "Lux" that the raspberry is surface rooting, so why trench to three feet, for the roots will not reap any benefit, as the drains would take much of the good food dug in. Peter should keep the good soil nearer the surface, and he will have better results than if it be put out of the reach of the roots. At Syon the soil is shallow, only twelve to fifteen inches deep in some parts, and resting on gravel. If we trenched such ground in the usual way our raspberries would cut a sorry figure. I may be told one need not bury the good soil, or that I might take out the gravel and put in good soil, but this would not be profitable where large quantities of raspberries are grown. My advice is, feed from the surface rather than from below, for the roots are not at the depth "Lux" advises.

Now for the second instalment. From the labour point of view "Lux" deprecates my advice as to cutting out old canes as soon as the fruits are cleared, because there is not time to do the work at the proper season. Are we to ruin our prospects of splendid new canes and big crops because of the time it takes to remove old ones? Really I expected better things from "Lux." We do not hesitate to summer-prune fruit trees even if time and labour are scarce at that season. We are much too fond, as gardeners, of excusing ourselves "because there was not time to do this or that." The removal of old raspberry canes does not take a great while, and as to the results of the system, it is patent to all that crowded plants cannot finish up the new growths for next year's fruit like those given plenty of air and light. By this system the whole energy of the plant goes to the upbuilding of fruiting canes and not to useless ones; "Lux" should also remember that the roots of raspberries are severely taxed if all canes are left till leaf-fall. In light soils, after a dry summer, the plants look none too well if they have borne a heavy crop and so have to be relieved as much as possible. With regard to economy I can assure "Lux" that in these days of high pressure practically every gardener has to study it; the private gardener has often more worry than the large market grower. I have never been fortunate or unfortunate enough to live in any garden where economy had not to be considered. I only wish we could have that same influence in the matter of outlay that Peter appears to have with "Lux." I conclude by hoping to retain "Lux's" good opinion though we may differ on raspberry culture.—G. WYTHES, *Syon Gardens*.

SUGGESTIONS.

HAVING read with great interest the "Morning Mixtures" in the GARDENERS' MAGAZINE, I have come to the conclusion that Peter is an indispensable part of it. Indeed, so prominent has this interesting and mysterious person become that the Mixture would be dry without him. It is not every lover of horticulture that possesses such a treasure, and perhaps that is why "Lux" is so proud of him; his type, however, is fast becoming extinct. It is all very well telling us what Peter does and when he does it, but what we gardeners of modern times want to know is, how he does it. How entertaining would be an illustration of Peter up-ending his potatos, or of "Lux" hiding behind him after being "egged on." One can imagine that when trouble is about Peter receives an extra "Well, what?" to help swallow the righteous indignation that pours in, while his master bravely shelters himself at his back. I wonder if "Lux" is allowed to roam about Peter's sacred domains without being overshadowed by a sense of trespassing. It would seem not, for I think if Peter would only consent "Lux" would yet be induced to receive a box of ferns from Mr. Druery, for deep down in the Luxian heart there is secret admiration for the lovely ferns, which far outshines the coldness of the ordinary horticulturist; he states that some of the crested forms are exquisite, but is this because Peter's form is crested, and "Lux" dare not say any other? What are Peter's ideas concerning good ferns,—and will "Lux" induce him to give his ideas on the "Lady Gardeners"?—FOI.

HORTICULTURAL LITERATURE.

I NOTICE that "Lux" in his Morning Mixture on page 179, asks "Why [illegible] not more gardeners read gardening papers?" I have no doubt that there are a great many in the profession who do not read the papers devoted to horticulture, and for various reasons. Some think themselves above taking the advice of others in a better position for acquiring knowledge and information on the different branches of the art. I for one believe in obtaining all the information possible on all subjects that may be of assistance to me and help to make me better able to properly fulfil my duties. I not only read with great interest and profit the GARDENERS' MAGAZINE, but I also preserve for future reference the [illegible] most valuable articles, by either pasting them into a blank page book or [illegible] the leaves entire; very many of the articles are too valuable to be read over once and then passed by—they need to be thought over. This, perhaps, may appear a rather childish method, but I find it very helpful, and therefore can with confidence recommend it to all young gardeners who like myself have not the room to [illegible] up all the numbers. We should get all the information possible from whatever source is available, we should make a real study of all that relates to the profession, not be afraid to ask reasonable questions of those older and more experienced than ourselves, strive to do our duty in every detail, and aim high. I am of opinion that many do not read periodical horticultural literature because their minds are not really in the work, and as soon as they are away from it gardening is almost the last thing that would be thought of until the next morning. Those in [illegible] positions with a number of young men under them should do all they can to encourage reading so that minds may be cultivated as well as gardens.—D. BURRIDGE, *Wellingborough*.

Laxton's Noble v. Royal Sovereign Strawberry.—I started the former on the first day of the New Year, and the latter a fortnight later, but Noble was ready on March 13 and Royal Sovereign on March 20. [illegible] remarkable freedom this season; Noble is rather short in the stem, and [illegible] throws the truss beyond the pot, while Royal Sovereign throws out a good [illegible] flower stalk, which is a distinct advantage. I do not consider either of very high flavour at this season, nor can we expect anything extraordinary; [illegible] Sovereign on our heavy soil is of very good flavour grown naturally. [illegible] Seedling is our next batch, and the fruits are of excellent flavour when not [illegible] too hard or too early in the season.—W. A. COOK.

WORK FOR THE WEEK.

WARM ORCHIDS.

SEED pods that ripen on orchids during the winter months are generally (or should be) put in small paper bags and hung up in a warm house for the effects of the sun to fully ripen them. If ripe, the present is a good time to sow seed, and amateurs, as a rule, are very anxious to raise seedling orchids. Seeds well ripened is the first essential. Select pots of orchids that are full of roots and the compost sweet, avoiding those overgrown with sphagnum, as seeds would be smothered before the year is out. Dendrobiums are the best sown on their own pots in the warmth, and the same applies to the raising of cattleyas and Lælia-cattleyas. Cypripediums are best sown on cypripedium pots, this ensuring their always being moist. Great care must be taken after sowing, and the watering done very cautiously. Always keep a record of dates, &c.

Imported plants should be examined and well watered before anything else is done to them; Dendrobium spectabile, of late introduction, will require stove treatment and syringing each morning to start it into growth. Dendrobium-phalænopsis Schröderianum may now be potted and placed in a warmer house, and given a slight syringing each morning until active growth takes place. Dendrobium formosum giganteum may also be potted and placed in the same house, but not syringed, as this being hirsute retains the water, and so causes the young growths to rot. Epidendrum radicans will now be growing, and will enjoy the syringe on suitable occasions; this must be placed in the hottest house and raised as near the glass as convenient, in order to bring ont the flower spikes. It also must be fumigated with XL. All occasionally, as a preventive against thrips and red spider. Renanthera coccinea thrives best in the heat, trained under the roof, close to the glass, and also enjoys the syringe. Vandas of the suavis and tricolor sections will be just showing for flower spikes, and it is of the utmost importance that syringing be done carefully, keeping the water out the axils of the leaves where the flower spikes appear. Aerides Fieldingi will also be showing spikes, this thrives well in pots; in the East Indian house magic paste must be put down where spikes are showing, and traps set for wood lice, such as potatos cut in halves and hollowed out in the middle; scale also attacks the spikes and causes malformation, vapourising is a good remedy for this. Lælia purpuratas should have finished their growth, and those that have not must be placed at the warm end of the house. Lælia tenebrosa can be served likewise. Lælia elegans that is failing to flower, and requires repotting, may be attended to; baskets are preferable to pots for this, as they can be suspended from the roof where convenient. Cattleya Schilleriana will be forming buds at the base of the sheath, and careful watering will be necessary; Cattleya dolosa will also be showing flowers, and require more moisture at the roots. Brassovola Digbyana is growing fast; it thrives well in a few degrees more heat than the cattleya house affords, placed in baskets, and suspended from the roofs in a light position. This is a very useful orchid for the hybridiser, owing to ite peculiar labellum.

Lælia anceps is now rooting fast, so the syringe must be used in the morning; shading over this species is not required; they need all the sun possible, a free circulation of air, and plenty of moisture. Miltonia Roezli, after such trying weather, is apt to fall a victim to red spider and thrips, so must be syringed often when the weather is warm, and must be fumigated; it thrives well in a warm house with plenty of moisture.

Shading will now require great attention, and also the firing, so as to keep the atmosphere in a right condition in all the houses. Cattleya houses will require damping in the morning and again in the afternoon.—T. STAFFORD, *Tyntesfield Gardens.*

THE FLOWER GARDEN.

A SELECTION of annuals and biennials should be made for sowing in the open borders, and many of the following may with advantage be added to those given in a former calendar, for besides embellishing vacant spots on borders they furnish flowers for indoor decoration. A few of the most serviceable for cutting should also find a place in the reserve garden, where the flowers may be gathered without unduly encroaching on the flower borders for the supply. Another sowing of sweet peas should be made to form a succession to those sown previously, as unless all seedpods be kept strictly picked off a succession of flowers cannot for long be maintained from the same plants, but by making successional sowings good flowers are secured, and a few fresh seeds may be saved from the early sowing if desired a consideration with some of the new and choice varieties. I prefer sowing in clumps or blocks of distinct colours, rather than in a mixture. Mignonette, of which scarcely too much can be grown, should also be sown freely; if a few seeds be scattered among roses in beds and raked in it forms a groundwork, and does not materially affect the well-being of the roses if kept within bounds and clear of the plants. Marvel of Peru, an old-fashioned tuberous-rooted plant may be easily raised from seed if sown now in slight warmth. These may be used as dot plants in mixed bedding or for filling vacancies in borders. Old roots saved from previous years may be treated somewhat like dahlias, or if potted up singly and started in slight warmth will make strong plants to go out at bedding time. For sowing on the open borders, which should be done during the next week or two, a good selection will be found in the following, in addition to those to be transplanted from frames already enumerated. Sunflowers of various heights; annual chrysanthemums, both single and double, all very useful; sweet scabious, helichrysums, Bartonia aurea, coreopsis, several kinds, all annuals excepting C. grandiflora, and this blooms equally well the first year; Clarkia elegans, C. rosea fl. pl., C. integripetala, C. pulchella, C. pulchella fl. pl., Collinsia bicolor, Centaurea cyanus, Convolvulus minor, eschscholtzias in variety, Godetia Whitneyi, G. Duchess of Albany, G. Apple Blossom, G. Lady Albemarle and G. Duchess of Fife; Linum grandiflorum coccineum, lavateras, remarkably lasting in a cut state, L. rosea splendens is a beautiful variety, and L. alba splendens is a white-flowered counterpart. The sweet sultans in three colours, white, purple and yellow, should not be omitted, nor several varieties of poppies, including Shirley vars; Phacelia campanularia, Canterbury bells in various colours for blooming next year; nasturtiums in several colours, and Whitlavia grandiflora. For trailing over trellises and similar spots use can be made of Tropæolum canariensis, Convolvulus major, and the tall-growing nasturtiums.

The beautiful blue Salvia patens, a valuable half-hardy perennial, may be raised from seeds sown in pots and placed in heat until germination has taken place. Old tuberous roots of the same may be potted up and treated as advised for Marvel of Peru. Lobelia cardinalis, if its increase be desired, should be split up and potted singly, giving a start in slight warmth. Young fuchsia plants intended for bedding must not be allowed to become root-bound and stunted in growth, but be given a shift in pots a couple of sizes larger, and kept growing steadily. Bedding calceolarias should be transplanted from the pits where struck somewhat closely together, into others, or temporary frames, stood on a firm base; use about six inches in depth of loam and leaf soil and plant six inches asunder. If made moderately firm the plants will lift with good balls attached for eventually transferring to the flower beds. Where the latter are standing empty these calceolarias may now be planted direct to their summer quarters, and be sheltered temporarily with a few branches or other covering, and in this way become well established before warm or dry weather sets in. Late planting is often the cause of calceolarias dying off suddenly in early summer, as hot weather sets in before they are thoroughly re-established. Violas may be similarly treated, but, being quite hardy, require no protection.—C. HERRIN, *Dropmore Gardens.*

HARDY FRUITS.

THE recent severe gales make us anxious about the hardy fruits; with us apricots appear to have set fairly well, but it is full early to note results. Fortunately for the peach and nectarine blooms, we have not had much frost after the rain, and it is this that does so much mischief by destroying the pollen. After biting east winds there is an early attack of aphis, and a great deal of this can be disposed of by early disbudding, and a large proportion of the new shoots are best removed at an early date. It is not well to disbud trees all at once, but it often happens the small weakly shoots not needed for next season are those most infested. I am a strong advocate for early disbudding, and some of the earliest trees will be ready to operate upon by the time this is in print. Apricots that have set many fruits will need early attention. Many advise leaving thinning till it can be seen what fruits will take the lead, but there are always a large number of badly-placed fruits that must be removed in any case, leaving the better placed fruits for later attention. It is yet full early to treat on stopping and disbudding, but the work on warm walls in the southern part of the country will soon be in full swing. I am much adverse to disbudding in cold weather, as I have seen the shoots left for next season blister badly, and this must be avoided and the work spread over several weeks. Some excellent growers advocate leaving the trees longer, in fact till the shoots are several inches long. I do not, as I have seen evil results from late disbudding. As regards thinning of fruits, it will be well to note the variety. Some are much stronger grown than others, and will carry more fruits. Our Hemskirk apricots always carry far too many fruits, also the smaller kinds, such as Breda and Kaisha or Syrian, and though we thin now we never thin sufficiently, as so few fruits drop.

A few words as to disbuddtng may not be out of place. The fruiting shoots should, whenever possible, have one or two well placed shoots left at their base for next year's fruiting wood, and in due course should be laid in. In training peaches or nectarines this space should always be allowed for, as the new wood to be good must be well developed. If the trees are at all thin, other shoots at from six to nine inches apart may be left on the fruiting wood, and a final shoot at the top. The best placed buds (above, not at a joint) must be left to develop the fruit. Any other shoots with fruit at the base should not be rubbed off, but stopped or pinched to two or three leaves, as this will assist ln building up the fruit at the base. The leading shoots on young trees will need care in selection, and those not needed for furnishing should be rubbed off; avoid crowding; select well-placed shoots on each side of the branches, not at foot or back of the branches; do not select shoots because they are strong, for if at all gross it is better to stop back and so obtain smaller growth; I fall to see the necessity for the hard cutting back often practised, as once the tree has made sufficient leaders to furnish it then allow it to grow freely, using the knife sparingly, as it far more profitable to cover a space in three years than in six, and strong rank growth is easily checked by pinching. Blister is a serious evil in some gardens, and it is well to remove affected leaves, and in bad cases mildew soon covers the parts injured, so must be dressed with a weak sulphur solution. Another evil is curl, and in many cases blackfly is the cause. Apricots need stopping when at all gross, as these strong shoots take an undue proportion of sap, and though with young trees leaders are needed for extension, select those best placed and of medium growth. The apricot fruits freely from spur growths and the aim should be to encourage this mode of growth, any shoots not needed to lay in being converted into spurs by stopping to the third or fourth leaf from the base. The apricot is so subject to loss of branches that it is advisable whenever possible to lay in shoots here and there in case of sudden collapse during the fruiting season.—G. WYTHES, *Syon Gardens.*

Intense Culture.—At a recent conference held by the Royal Arsenal Co-operative Society the question of co-operative agriculture was discussed by such well-known authorities as Dr. Paton, Professor Bottomley, and Mr. H. Wolff. It was proved beyond question that by intense culture agricultural land could be made more productive and profitable than it is at present. This is a point we have long urged, for we have seen many succeed when they have "gardened" their farms instead of starving them. Professor Bottomley, of King's College, drew attention to one of the many small agricultural colonies now succeeding in various parts of the country; this was at Pembury, near Tunbridge Wells, where the villagers, by means of combined credit, and borrowed capital took a farm where the two previous occupiers had been ruined. They all succeeded, however, save the one who took over the hop garden. The co-operators buy in common their seeds, their manures, and machinery, and sell in common their produce in Tunbridge Wells, and the land which previously failed to maintain two men and a boy now supports eighteen adult labourers.

Barley Wine.—The British Consul at Naples, in his last report, refers to the subject of the production of artificial wines from barley, which he mentioned in his report for 1896, and then received some attention in this country. He now summarizes the process, and compares the revolution likely to be caused in wine-growing countries by this discovery to that caused by the discovery of beetroot sugar. It seems that a large factory is at work at Wandsbek, near Hamburg, producing the so-called Malten-Weine, which have the characteristics of the wines of Southern Europe, owing to the entirely new process of fermentation to which they are subjected. The factory is said to produce about a quarter of a million gallons per annum. The discovery was due to Pasteur, who, however, never carried it beyond the theoretical point; and it was left to Mr. Hansen, a Dane, and Dr. Sauer, a German bacteriologist, to carry Pasteur's theory into practice. The barley is malted and carried to the point of fermentation, when lactic acid and vinous ferments are introduced, the mass being subjected to sundry variations of temperature. Sherry, port, Tokay, and Malaga have thus been closely imitated. When fermentation is completed, the liquor is put into huge vats of about 4,500 gallons, and thence into casks of 1,500 gallons, where it is artificially matured by being raised to a high temperature. The transformation of the substances which give the liquor its taste and bouquet is thus accomplished in a few weeks, instead of requiring as many years, and, at the same time, all extraneous matter derived from the ferments is sterilised and rendered innocuous. The liquor can then be drawn off into small casks or bottles, and in three or four months it is ready for consumption. These artificial wines have a large percentage of alcohol, 19 per cent., or even more, being derived wholly from fermentation.

EXHIBITIONS AND MEETINGS.

THE NURSERYMEN AND MARKET GARDENERS' HAILSTORM INSURANCE CORPORATION (Limited).

THE third ordinary general meeting was held at Simpsons' (Limited), on Thursday, March 31, when the following report was presented:—

The directors, in submitting to the shareholders their third annual report on the business of the corporation for the year ending 23rd February, 1898, together with the audited accounts, have to state that no alteration in the amount of capital issued has taken place during the past year.

HAILSTORMS.—The hailstorms which occurred during the year 1897 will long be remembered for their extreme violence, for the large area over which they fell, and for the devastation and ruin which they wrought, more than eighty nurseries being very seriously damaged. On the 16th April, 1897, severe storms caused considerable damage to glass and crops at Luton, Dunstable and Bedford, as well as in Lincolnshire, Cambridgeshire, and North Herts. On the 24th June, 1897, hailstorms of unprecedented violence occurred simultaneously in Essex, Hertfordshire, and Middlesex, the results being most disastrous at Chelmsford, Ingatestone, Ponder's End, Enfield Highway, Waltham Cross, Enfield, New Barnet, Heston, near Hounslow, and Harrow. The glass-houses at over sixty nurseries were wrecked by these storms, and crops in several localities were completely destroyed. Many of the nurserymen, market gardeners, and farmers were not insured, their losses amounting to many thousands of pounds. In Essex alone the damage to glass and crops was estimated at over £50,000. On the other hand, the owners of thirty nurseries whose glass-houses were severely damaged, had insured with this corporation, who immediately surveyed the properties, assessed the damages, and paid the claims within six days of the storms occurring. When it is known that these nurseries are situated at considerable distances from each other, that the total length of the glass-houses exceeds twenty-five miles, that every house had to be carefully examined, and every pane of glass broken or cracked by hail counted, the fact that all were surveyed, the claims satisfactorily assessed (one amounting to £886 1s. 0d.) and settled within six days, demonstrates the prompt and satisfactory manner in which this corporation carries on its business. The vast amount of damage done by these hailstorms, together with the prompt and satisfactory manner in which the claims were assessed and paid, have resulted in the operations of this corporation becoming much better known and appreciated.

The directors are also pleased to draw attention to the fact that though the corporation had only been established so short a time the whole of the claims were paid without any further call on the shareholders being made. Every possible effort has been made to inform the public of the special advantages and reduced premiums offered by this company, and the directors are gratified to be able to announce that the premium income this year is more than 50 per cent. over that of the preceding year. The directors again desire to draw attention to the special advantage of insuring with this corporation, viz.: that those insured can replace immediately their own glass broken by hail, the corporation paying them at the rate per square foot at which the glass is insured. Another special advantage, and of which several insurers are availing themselves, is that of being able to cover wholly or partially the value of the contents of their glass-houses by increased insurance of their glass—an advantage offered by no other insurance company. In accordance with Clause 92 of the Articles of Association, no directors' fees have been paid.

REVENUE ACCOUNT.

Income.—The income from premiums amounted to £1,360 17s. 0d., which, with dividends derived from investments, £45 7s. 3d., and transfer fees, 7s. 6d., made the total income £1,406, 11s. 9d.

Expenditure.—The total sum charged against revenue was £2,228 11s. 11d., comprising:—

Claims paid £1,532 17s. 5d., less reserve £300	£1,232	17	5
Commission on insurances	142	2	8
Working expenses	261	11	2
Loss on sale of investments	8	16	8
Formation expenses, amount written off, ...	80	0	0
Reserve for unexpired risks, ...	500	0	0
10 per cent. written off office furniture and fixtures ...	3	4	0

The necessity for setting aside £500 for unexpired risks is apparent from the fact that the whole of the claims paid (£1,532 17s 5d.) were on policies unexpired at the end of February, 1897, the premiums on which went to the credit of that year's account.

BALANCE SHEET.

Capital and Liabilities.—

Shareholders' capital, 5,000 shares of £5 each	£25,000	0	0
Called and paid up, 10s per share	2,500	0	0
Sundry creditors	5	5	0

Assets.—Of the paid-up capital, after deducting balance of formation expenses and cost of furniture, £1,085 10s. 9d. is invested in 2¾ per cent. Consols, amounting at cost price to £1,151 6s. 6d.; £300 in 3½ per cent. Liverpool Corporation Stock, costing £407 13s. 6d.; £129 16s. 2d. India 3 per cent. Stock, costing £143 6s 6d.

Owing to the number of claims paid and the large reserve set aside for unexpired risks the directors do not propose to declare any dividend for the past year, whilst they consider it desirable to state that in consequence of the large increase in the income the corporation is, in their opinion, at the present time in a much stronger financial position than at any previous period of its history. In expressing this opinion the directors desire to add that they are thoroughly satisfied with the result of the last year's business, and to express their thanks to the various representatives of the corporation for their efforts during the year.

The report was passed unanimously, and the retiring directors, Messrs. Robert Piper, Edmund Rochford, William Sams, F. Sander, N. N. Sherwood, and P. C. M. Veitch, were re-elected. The auditors, Messrs. Baker, Haward, and Watson, were also re-elected.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY,

March 29 and 30.

FOR all-round excellence we have seldom seen a better show than that held in the Dome and Corn Exchange, on the above date. So general was the competition that no more exhibits could possibly have been staged.

In the open classes Mr. J. Hill, gardener to C. Wallis, Esq., Springfield, Withdeane, was first for a well-arranged group, which, although not containing any choice subjects, was so well set up as to beat that of Mr. G. Miles, Dyke Road Nursery, Brighton, who had some well-grown crotons, clivias, dracænas, and palms, backed by large plants of Acacia cordata. Tables of flowering and foliage plants were also good, and here Mr. G. Miles was first, having for his most notable plants Begonia Gloire de Lorraine and pot roses. Mr. [illegible], gardener to E. A. Wallis, Esq., Upper Lewes Road, ran the above very close. The third prize table from Mr. J. Harper, gardener to E. A. Tucker, Esq., Vernon Place, Preston, contained some good caladiums and gloxinias. Mr. Harper was first for a collection of orchids, having Lycaste Skinneri splendens, Sophronites coccinea (very bright), Cattleya Trianæ, and Lælia harpophylla especially good. Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Mount Hurry, Preston, followed, his Cœlogyne cristata, Oncidium sphacelatum, Cypripedium Rothschildianum, C. philippinense, Cattleya citrina, being good. A specially interesting feature was the dressing of a mantel-piece and hearth with plants. Mr. G. Miles won with a very simple arrangement, containing Begonia Gloire de Lorraine, small palms, ferns and the common primrose. Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, Withdeane, came second. Hyacinths in pots were good, Mr. House, gardener to Sir F. Mowatt, K.C.B., Withdeane Hall, winning for twelve. Mr. E. Anderson, gardener to B. [illegible], Esq., Melodia, Preston Park, won for twelve pots of really good tulips. The lilies of the valley were more numerous and better than usual, Mr. A. E. Golding, gardener to H. St. George Voules, Esq., Dyke Road, just beating Messrs. W. Miles and Co., Hove. Mr. J. House won for six pots of freesias. Lachenalias were excellent; we have seldom seen L. tricolor better than those from Mr. J. T[illegible], gardener to Sir Grenville Smythe, Wickhall, and from Mr. J. Hill, gardener to C. Wallis, Esq., Withdeane. Mr. W. E. Anderson was well ahead in a strong class for six pots of mignonette. Mr. Harris, gardener to Mrs. Eversfield, Denne Park, Horsham, won for violets, staging the true Neapolitan and just beating Mr. J. Hopkins, High Cross, Framfield. Mr. G. Miles was first for double flowered primulas, and Mr. G. F. Bunney, Brighton, first for the same number of single-flowered plants. In a class for six auriculas, Mr. J. Pearl, gardener to B. Y. Bevan, Esq., Withdeane, won with large plants of alpine varieties, but not of good quality. Mr. M. Tousle, gardener to F. Barchard, Esq., Little Horsted, was well in front for six hydrangeas.

The table plants were good and of neater growth than usual, Messrs. W. Miles and Co., Hove, winning, and also first for twelve pots of well-flowered narcissus. There were some remarkably good cyclamen, Mr. C. Murrell gardener to Mrs. Jenkins, Burgess Hill, being awarded first prize. Cinerarias were smaller than usual, but clean; Mr. G. Hart, gardener to H. Head, Esq., Buckingham, Shoreham, won for twelve pots; but genistas were better and far more numerous than usual. The best dozen came from Mr. Head, the Drive Nursery, Brighton. Spiræas were also a great improvement, Mr. G. House, gardener to Sir F. Mowatt, K.C.B., winning for twelve grand pots. Amaryllis were not numerous, but the six winning pots from Mr. G. House were of exceptional merit, and we have not seen these showy spring flowers better done. We did not think the greenhouse azaleas were sufficiently finished; the best nine came from Mr. J. Hill, gardener to Clarkson Wallis, Esq., Springfield, Withdeane, closely followed by Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, and who has generally had some grand examples. In the Ghent and Mollis section there was great improvement, the six plants from Messrs. W. Miles and Co., Hove, would have been hard to beat at any exhibition. Pot roses were better than we have seen them here for some years. Mr. A. Polley, gardener to J. Dunk, Esq., Rose Villa, Stamford Avenue, winning with six good specimens, the best being La France, Marie Baumann, Niphetos, Madame Cusin, Rubens, and Heinrich Schultheis. Callas from Mr. E. Anderson were exceptionally well flowered and large for the size pots used.

The class for twelve bunches of cut narcissus is always strongly contested. This year Mr. J. Harper, gardener to E. A. Tucker, Esq., Vernon Lodge, Preston, had some really good blooms of Golden Spur, Sir Watkin, Henry Irving, Princeps, Incomparabilis Leedsi, Cynosure, Pallidus præcox, Queen Bess, and rugulosus (Jonquil). Mr. M. Tourle, gardener to F. Barchard, Esq., Little Horsted, who had such a magnificent stand last year, was a close second, followed by Mr. J. Hopkins, gardener to L. Thornton, Esq., Framfield. Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Preston, had some good cut flowers, the most showy being Eucharis amazonica, Phaius Sanderiana, Cypripedium Rothschildianum, C. Boxalli, and Boronia heterophylla. There were six boxes of twelve cut roses, the first award going to Mr. G. W. Piper, The Nurseries, Uckfield, for a very clean lot of blooms, consisting of Maman Cochet, Rubens, Madame Willermoz, Jean Ducher, Alba Rosea, Catherine Mermet, Kaiserin Augusta Victoria, Bridesmaid, Souvenir d'Elise Vardon, Comtesse de Nadaillac, The Bride and Madame Edouard Helfenbein; Mr. G. Miles second. An arrangement of natural flowers suitable for a dinner table called out some good stands. First prize was awarded to Mr. E. Meachen for an arrangement of mixed flowers, that did not commend itself to many tastes to nearly the same extent as the graceful and simple arrangement of narcissus and foliage, from Mrs. M. Tourle, The Gardens, Horsted Place.

There were a large number of non-competitive exhibits. Messrs. J. Cheal and Sons, Crawley, showing plants and fruit; Mr. G. W. Piper, The Nurseries, Uckfield, had cut roses in quantity; staging Sunrise, a new tea rose not yet in commerce, and most distinct. Mr. A. Kemp, Coolhurst Gardens, Horsham, [illegible] some good fruit and potatos; Messrs. Cutbush and Son, Highgate, N., a [illegible] stand of hard-wooded plants and cyclamen; Mr. W. Goodcliffe, [illegible] Nursery, Worthing, a grand group of ferns; and Messrs. Balchin and Sons, Brighton and Hassocks, a stand of azaleas, hydrangeas, ericas, amaryllis, &c.

SOUTHAMPTON, March 29 and 30.

THE first spring exhibition held under the auspices of the Royal Southampton Horticultural Society took place on the above dates in the Victoria Hall. For a first exhibition it was a great success from a horticultural point of view. The competition in most of the classes was keen, while the exhibits left little to be desired. In front of the orchestra were two capital collections of [illegible] arranged with ferns and foliage plants, and which were quite the centre of attraction. Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak Park, [illegible], was an easy prize winner with freely flowered examples, amongst which the following were conspicuous: Cymbidium Lowianum, Dendrobium [illegible], Odontoglossum crispum, O. Pescatorei and O. triumphans, Miltonia [illegible], Lycaste Skinneri, and Lælia flava, together with several profusely flowered [illegible] of Dendrobium nobile, produced a brilliant effect. Mr. A. Pragnell, gardener to Captain Shaw Storey, Elm Lodge, Bursledon, was a good second with [illegible] choice examples neatly staged. For a collection of miscellaneous plants [illegible] for effect there were three competitors, all staging creditably; Mr. E. Carr [illegible] again successful with good material somewhat closely arranged, Mr. W. [illegible] gardener to Miss Todd, Sidford Lodge, Shirley, a good second; Mr. E. [illegible] florist, Shirley, third. Stove and greenhouse plants were well represented. [illegible] eight specimens Mr. Peel was the most successful, staging healthy [illegible]; Mr. [illegible] freely flowered greenhouse rhododendrons, anthuriums and azaleas; [illegible] second, Mr. Carr third. Azaleas were freely contributed; for four [illegible]

Mitchell, gardener to W. Willis Fleming, Esq., Chilworth Manor, was an easy winner; Mr. C. Horsey, gardener to J. C. E. D'Esterne, Esq., Elmfield, Millbrook, second. Mr. Longster, Burgess Street Nurseries, had the best single specimen azalea. Mr. Mitchell contributed grandly flowered Deutzia gracilis in the class for this plant. Cinerarias were well shown by Mr. Horsey, who won first prize for four, staging also fifty plants "not for competition," for which a "highly commended" card was given. Mr. Wills was the most successful exhibitor of hyacinths, staging fairly good specimens in the class for twelve. Primulas, cyclamens and lily of the valley were well staged, Mr. Carr securing leading honours in the two former classes, and Mr. Mitchell winning in the latter.

Cut flowers were interesting if not numerous, Mr. Carr winning first prize for an epergne or stand neatly draped with choice orchids interspersed with ferns and other greenery; Miss Wadmore, Basingstoke, securing a similar recognition for a basket of cut flowers tastefully arranged. Contributions of miscellaneous plants not for competition were especially deserving of notice. Mr. B. Ladhams, Shirley, had a pleasing group of lilacs, zonal geraniums, hardy azaleas, blue primroses, cut narcissus and a choice collection of alpines all tastefully arranged. Messrs. Brightman and Andrews, Southampton, contributed azaleas, ferns, lily of the valley, &c. Mr. E. Wills had a really fine display of well grown nursery sttock. Messrs. Longster Bros. had a similar although smaller group. Mr. Fuidge, hon. secretary, also deserves some recognition for the tasteful and efficient manner in which all the arrangements were made.

THE PEOPLE'S PALACE HORTICULTURAL SOCIETY,

March 31.

The first of a series of four exhibitions during the present year took place at the People's Palace, Mile End, on the above date, and was most satisfactory, as showing a marked advance in the culture of the hyacinth, tulip, and narciss. The tables placed in the Queen's Hall were full of highly creditable exhibits, and one of the leading competitors, who resides in the City Road, showed among his three specimen plants one of Araucaria excelsa, nearly four feet in height, and of proportionate diameter, furnished with branches down to the pot, and in fine health, which, he stated, he grew in a window. Tables of spring-flowering plants were a pleasing feature, and among the hyacinths there were excellent specimens of King of the Blues, this being largely shown. Keizer's Kroon, Proserpine, and White Pottebakker are the favourite early single tulips. There were excellent pots of Polyanthus narcissus, and such single daffodils as Horsfieldi. Emperor, Empress, Golden Spur, and others bore well-developed flowers. In most of the leading classes there were good entries. Once a month some competent person delivers a lecture to the members on some topic related to East-end gardening; and a social monthly meeting is also held, to which the members bring any plants or flowers they may have in good character, and give their method of treatment. These meetings are said to be productive of great good, and operate to maintain the interest of the members in the work of the society.

READING GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

Mr. W. H. Lees, of The Gardens, Trent Park, New Barnet, read a paper on "Profitable Orchids" before the members of the above association on Monday evening last, Mr. C. B. Stevens presiding. The formal business having been transacted and a sum of £5 5s. been voted to the special fund raised by the Reading Horticultural Society, the president called upon Mr. Lees to give his paper. In introducing his subject the essayist said that it was not his intention to treat the subject from a market grower's point of view, as the title seemed to imply, but from that of the private gardener, dealing with those kinds most suitable for cutting and decorative purposes. The general routine of the cultivation of odontoglossums, cattleyas, lælias, dendrobiums, cœlogynes, calanthes, cypripediums, oncidiums, was briefly dealt with under the following headings: Ventilation, heating, staging, watering, manuring, potting, compost, insects, fumigating, &c. The following orchids were recommended for the purpose already named: Odontoglossum triumphans, O. hystrix, O. Halli, O. odoratum, O. crispum, O. Rossi, O. Edwardi, O. Harryanum, O. Pescatorei, Cattleya Percivaliana, C. Trianiæ, C. Mendeli, C. Mossiæ, C. gigas, C. Dowiana, C. Gaskeliana, C. labiata, C. Skinneri, C. Harrisoniana, Lælia purpurata, L. elegans, L. harpophylla, L. anceps, L. autumnalis, Dendrobium nobile, D. Wardianum, D. phalænopsis Schröderianum, Cœlogyne cristata, C. c. Lemoniana, Cypripedium insigne, Oncidium tigrinum, &c. An interesting discussion ensued, in which Messrs. Martin, Stanton, Turton, Woolford, and Bound, took part. A splendid exhibit of orchids was made, which greatly added to the interest of the meeting, and helped to illustrate many of the remarks made by the speaker. Those who contributed the plants and cut flowers were Mr. Woolford, gardener to Alfred Palmer, Esq., East Thorpe (dendrobiums, cypripediums, cœlogynes, odontoglossums, and oncidiums); Mr. J. Pound, gardener to Dr. May, Caversham (Dendrobiums fimbriatum oculatum); Mr. G. A. Parsons, Oxford Road (dendrobiums); whilst Mr. Stanton, Park Place Gardens, exhibited some spikes of bougainvilleas. A hearty vote of thanks was passed to Mr. Lees and to those members who had been the means of bringing together such a beautiful collection of bloom.

NEW PLANTS AND FLOWERS.

PHAIUS NORMAN.

This fine hybrid, recently described and figured in these columns, was exhibited by Messrs. B. S. Williams and Son, Holloway, at the R.B.S. spring show of March 30; a botanical certificate was awarded.

ZYGOPETALUM PERRENONDI.

An attractive zygopetalum and a hybrid between Z. Gautieri and Z. intermedia. The sepals and petals are green barred with dark green and dull purple. Lip large, bright violet purple veined with dark purple. B.C., R.B.S., March 30. Messrs. B. S. Williams and Son.

ODONTOGLOSSUM TRIUMPHANS INTENSE.

A very fine form of a well-known orchid; it has large highly-coloured flowers, the rich brownish-crimson blotches showing up splendidly on the yellow ground. The segments are broader than usual, though of good length. B.C., R.H.S., March 30. Messrs. H. Low and Co., Enfield.

CYMBIDIUM EBURNEO-LOWIANUM.

This fine hybrid is now quite well known. It is the result of crossing C. eburneum with C. Lowianum; the large flowers have ivory-white sepals and petals, and a white lip on which is a conspicuous horseshoe-shaped crimson mark. The flowers are also fragrant. B.C., R.B.S., March 30. Messrs. H. Low and Co., Enfield.

CLIVIAS.

Mrs. A. Sykes.—A splendid clivia of fine shape and the richest orange-scarlet shade along the upper halves of the segments. The throat is yellow, tinged with orange. Flowers of the largest size; truss large. F.C., R.B.S., March 30. Messrs. J. Laing and Sons, Forest Hill.

O. O. Wrigley.—A handsome variety with immense flowers and broad segments. The colour is intense orange-scarlet with a pale orange throat. F.C., R.B.S., March 30. Messrs. B. S. Williams and Son, Holloway.

NARCISSI.

Mrs. Walter Ware is a fine bicolor Ajax form, with handsome frilled trumpet of a golden yellow shade, and a spreading creamy perianth. A bold variety. F.C., R.B.S., March 30. Messrs. Barr and Son.

J. B. M. Camm.—This is a well-known Ajax daffodil, with pale sulphur trumpet and white spreading perianth. One of the best of the whitish forms. F.C., R.B.S., March 30. Messrs. Barr and Son.

ASPLENIUM MAYI.

A useful decorative fern with fronds about ten inches long, pinnate, and with the pinnæ deeply and narrowly cut. The colour of the frondage is deep green, and the surface is smooth and polished. This should prove a most useful asplenium for house decoration, as it could be readily sponged if necessary. B.C., R.B.S., March 30. Mr. H. B. May, Edmonton.

PTERIS GRACILIS MULTICEPS.

A graceful pteris, with finely divided and crested tips to the long depending pinnæ. This is an extremely pretty variety, being an elegant divided and crested form of the now well-known Pteris serrulata gracile. B.C., R.B.S., March 30. Mr. H. B. May, Edmonton.

ASPLENIUM HILLI.

A handsome spleenwort, with stout fronds about fifteen inches long, and much divided like lace-work. It is a bulbiferous form, and intermediate between A. biforme and A. Belangeri, the influence of the latter being very evident in the minute divisions. B.C., R.B S., March 30. Messrs. J. Hill and Co., Edmonton.

HYACINTHS.

Cineraria has bold stout spike and rich blue bells, the latter with lighter centre almost shading to white. A very effective hyacinth.

Ball of Gold has very large bells, with broad segments of a clear, soft sulphur-yellow. These are borne freely on a stout, compact spike. The title scarcely applies to the variety, for the colour is not golden. F.C., R.B.S. to each, March 30. Messrs. W. Paul and Son, Waltham Cross.

CAMELLIAS.

Pride of Waltham.—A fine pale pink variety, freely veined and tinted, with deep flesh pink. The flowers are large and handsome.

Boadicea.—A big, bold flower, with rounded segments; colour, blush pink with heavy veinings of rich and bright rose-pink. F.C., R.B.S., to each, March 30. Messrs. W. Paul and Son, Waltham Cross.

SOW THE SEEDS of good health, prune and strengthen sickly and weak branches of the tree of life, with the aid of Holloway's World Renowned Pills and Ointment. The Pills improve the appetite, strengthen the digestion, and regulate the liver. Under treatment with the Ointment, bad legs become sound, scorbutic skins cast off their scales, and scrofulous sores cease to annoy. When rubbed upon the abdomen, it checks all tendency to irritation in the bowels, and averts diarrhœa and other disorders of the intestines, frequently prevailing through the summer and fruit seasons. Heat bumps, blotches, pimples, inflammation of the skin, and enlarged glands, can be effectively overcome by using Holloway's remedies, according to instructions given to each purchaser.—[Advt.]

THE PATENT SPHINCTER GRIP
ARMOURED HOSE.
"HERCULES" Brand.
CANNOT
KINK
THE ORIGINAL ARMOURED HOSE.

HIGH CLASS UN-ARMOURED GARDEN HOSE.

THE CINCHONA IN INDIA.

(Concluded from page 217.)

Collection of Bark.

In Sikkim, the periodical crops of bark will be got from thinnings and prunings from the fourth or fifth year up to the twelfth year, when the trees will be at their best, and it is then more profitable to totally uproot, and plant on fresh land, than to allow them to remain longer in the ground. The plan originally laid down was to plant out 2,400 acres, and afterwards keep up this area by uprooting 200 acres annually and planting as much; but factory demands and other circumstances often compelled modifications, although in the main the plan was adhered to till of late years, when it was found that bark for the factory could be got from Travancore and elsewhere at less than it cost to grow in Sikkim, where planting operations have consequently been restricted of late. So Sikkim is gradually becoming more of a manufacturing than a cultivating centre for the East India cinchona industry. When the trees are uprooted, the bark of the larger roots, stems, and thick branches, is collected by peeling or beating off with wooden mallets. The smaller branches and roots are peeled by pulling them smartly through between two upright sticks stuck firmly and closely together in the ground when the bark comes away in ribbons. One or two heavy and cumbrous machines have been invented for collecting this small bark, but none has answered better than the two simple sticks stuck in the ground, which reminds one of the old story of the inventor and his cabbage-cutting machine, which, the inventor declared, after all its good points had been explained and praised, cut cabbages nearly as well as an old kitchen table knife did. The bark is at once spread out to dry either in open or heated sheds according to the weather, and when properly dried and protected from damp and rot, will remain chemically unchanged for scores, or perhaps hundreds of years. Although the total uprootal plan is the most profitable for Sikkim, it is by no means so for countries geographically better situated for the growth of cinchonas. On the Nilgiris, for instance, where several species thrive to perfection, the usual plan of collecting is that devised by the late Mr. McIvor, the first superintendent of the Madras Government Plantations, and usually known as the stripping process. By it the half of the stem bark is taken from the standing trees in vertical strips of about an inch and a half in width, from the collar up to the lower branches, or as high as may be thought advisable. If the trees are quite healthy the bark will part from the wood, at the proper season, of course, with the greatest ease, and leave the cambium layer uninjured.

Immediately after the stripping, the stem is covered thickly with moss, or other soft substances, to exclude the weather. From the edges of the cuts, and all over the surface of the cambium layer, the new bark forms evenly and with marvellous rapidity. In a year, or less, the renewed bark will be as thick as the original, and the remaining strips of original bark may be taken. Afterwards there may be annual collections of renewed bark for a considerable number of years. It is a curious fact that the renewed bark is much richer than the original in quinine, and consequently more valuable—often to the extent of 25 to 50 per cent. The plan requires generous treatment of the trees in the way of manure and cultivation, as only trees in vigorous growth will stand it; but it well repays the extra expenditure. For this discovery, and many other things, the cinchona industry is heavily indebted to Mr. McIvor, perhaps more so than to any other man. Several modifications of his stripping plan have been tried, but none has succeeded so well. Perhaps the best of them is the shaving plan of the Dutch in Java. By it the outer half of the bark, all round the stem, is removed with spoke-shaves, and the stem covered up in McIvor's way. As it is well known that the great proportion of the alkaloids is located in the outer half of the bark, and very little in the inner, it is claimed for this plan that the whole of the useful factory bark can be removed by it, and the useless left behind to carry on the life-work of the tree.

It was also supposed to be less injurious to the trees, but, according to my experience, it is quite the other way. McIvor's plan, which was in operation many years before it, no doubt suggested it to the Dutch. Coppicing was tried in Sikkim, but was a commercial failure, as by it we lost the bark from the original roots, which usually amounted to quite one-third of the whole out-turn. As the coppice shoots grew, they threw out new roots for themselves and the old ones died, and their bark was lost to us for ever.

Manufacture of Quinine.

After the collection of the bark its plan of disposal had to be decided. The easiest plan, which also would have been the most profitable for the plantation for many years, would have been to sell the bark in London, and buy back the manufactured sulphate of quinine. But the Government, both in India and at home, were anxious to have it worked up at the plantations, so as to save the heavy transport charges, and at the same time render India independent of other countries for her quinine supplies. The Madras plantations being the oldest, were the first to attempt local manufacture, but after some years of continual failure gave up the scheme as hopeless. Their experiments were conducted by Mr. Broughton, the quinologist to the Madras Government, who did most excellent and useful work in his laboratory, but did not succeed so well in the factory. So his experimental factory was shut up and the bark sent for sale to London, where for many years it fetched most profitable rates. But the Bengal Government, who began their manufacturing experiments a little later than Madras, persevered till success was attained. Now Madras finds it pays better to adopt the Bengal plan of local manufacture than to ship the bark. There were numerous processes tried at the Bengal plantations, but it will suffice to give brief details of the three principal. The first, which was started in Madras, and afterwards tried in Bengal, was supposed to be the process then worked by the European makers of sulphate of quinine, who, however, gave no information on the subject, but jealously guarded their trade secrets, which, of course, was perfectly legitimate and business-like, but plainly showed that no help in starting quinine making in India was to be had from them. By this plan the alkaloids were extracted from the bark by repeated hot digestion with water mixed with a little sulphuric acid, and afterwards precipitated from the acidulated liquours with milk-of-lime. The precipitate was collected on calico filters, dried, powdered, and treated with strong hot spirits of wine to dissolve out the soluble alkaloids from the insoluble sulphate of lime which formed the bulk of the precipitate. Then the alcohol, containing the alkaloids in solution, was mixed with a little dilute sulphuric acid and recovered by distillation for future use, and the remaining acidulated liquor treated in the ordinary way for the recovery of the quinine and other alkaloids. But the plan proved a miserable failure both in Madras and Bengal. It missed more than half the alkaloids, and was tedious and costly to work. This was unfortunate, as the chemicals required to work it were mostly procurable on the spot, an important consideration in a mountainous country, where carriage is difficult and expensive. Lime was found and burnt on the place; carbonate of potash was made from the ashes of Artemisia and other indigenous plants; and the alcohol from Indian corn grown [illegible] squatters. The method of spirit-making adopted was the one in [illegible] among the hill tribes of the Eastern Himalayas, and differs from [illegible] process for making grain spirit in dispensing with the malting-step. The Indian corn is coarsely ground, and heated till soft in as much water as it will soak up; then mixed with a small quantity of powdered ferment-cake, and put into baskets lined with bracken-fronds to ferment. When sufficiently fermented, the moist mass, with a little added water, is treated in the usual way in an ordinary still. Afterwards, the weak spirit thus got is put through a rectifying still to get it up to 60 degrees over proof, the strength required. The ferment cakes are made on the same principle as mushroom spawn, and consist of rice and the fresh fleshy roots of a rather pretty-flowering Himalayan shrub—Polygala arilata—pounded [illegible] together. The soft mass is made into round cakes an inch thick, and [illegible] with a little old ferment cake in powder. The cakes are then packed away loosely among fern fronds in a warm place, and the light excluded till the ferment fungus has permeated them, when they may be dried and stored for future use. It is a matter of common belief among all the tribes that whoever makes these cakes will be ever after afflicted with sterility, so only women beyond a certain age will make them. I do not suppose there is any real foundation for this idea, but in dealing with eastern people it is always wise to respect their little prejudices and superstitions.

The second plan to be described was a very simple one, and inexpensive to work, but unfortunately, like the last, missed a large proportion of the alkaloids. For a good many years, however, it did good, useful work, while a better was being devised. It was never used in the manufacture of sulphate of quinine, but only for making the medicine known in India as cinchona febrifuge, which is a mixture of the whole of the alkaloids, both amorphous and crystallisable, found in the Red Bark. It is not so elegant a preparation as sulphate of quinine, but is an excellent substitute for it in malarial fevers. In fact, some of the best Indian doctors prefer it. For some years it was sold at less than quarter quinine rates, and was a great boon to poor people. In making it the powdered bark was repeatedly macerated in wooden tubs, with a very dilute muriatic acid, for a few days at a time, and the resulting liquors mixed with a solution of caustic soda to precipitate the alkaloids they had dissolved out or the bark. After standing twenty-four hours, the precipitate was collected on filters, purified, dried, and powdered, which completed the operation.

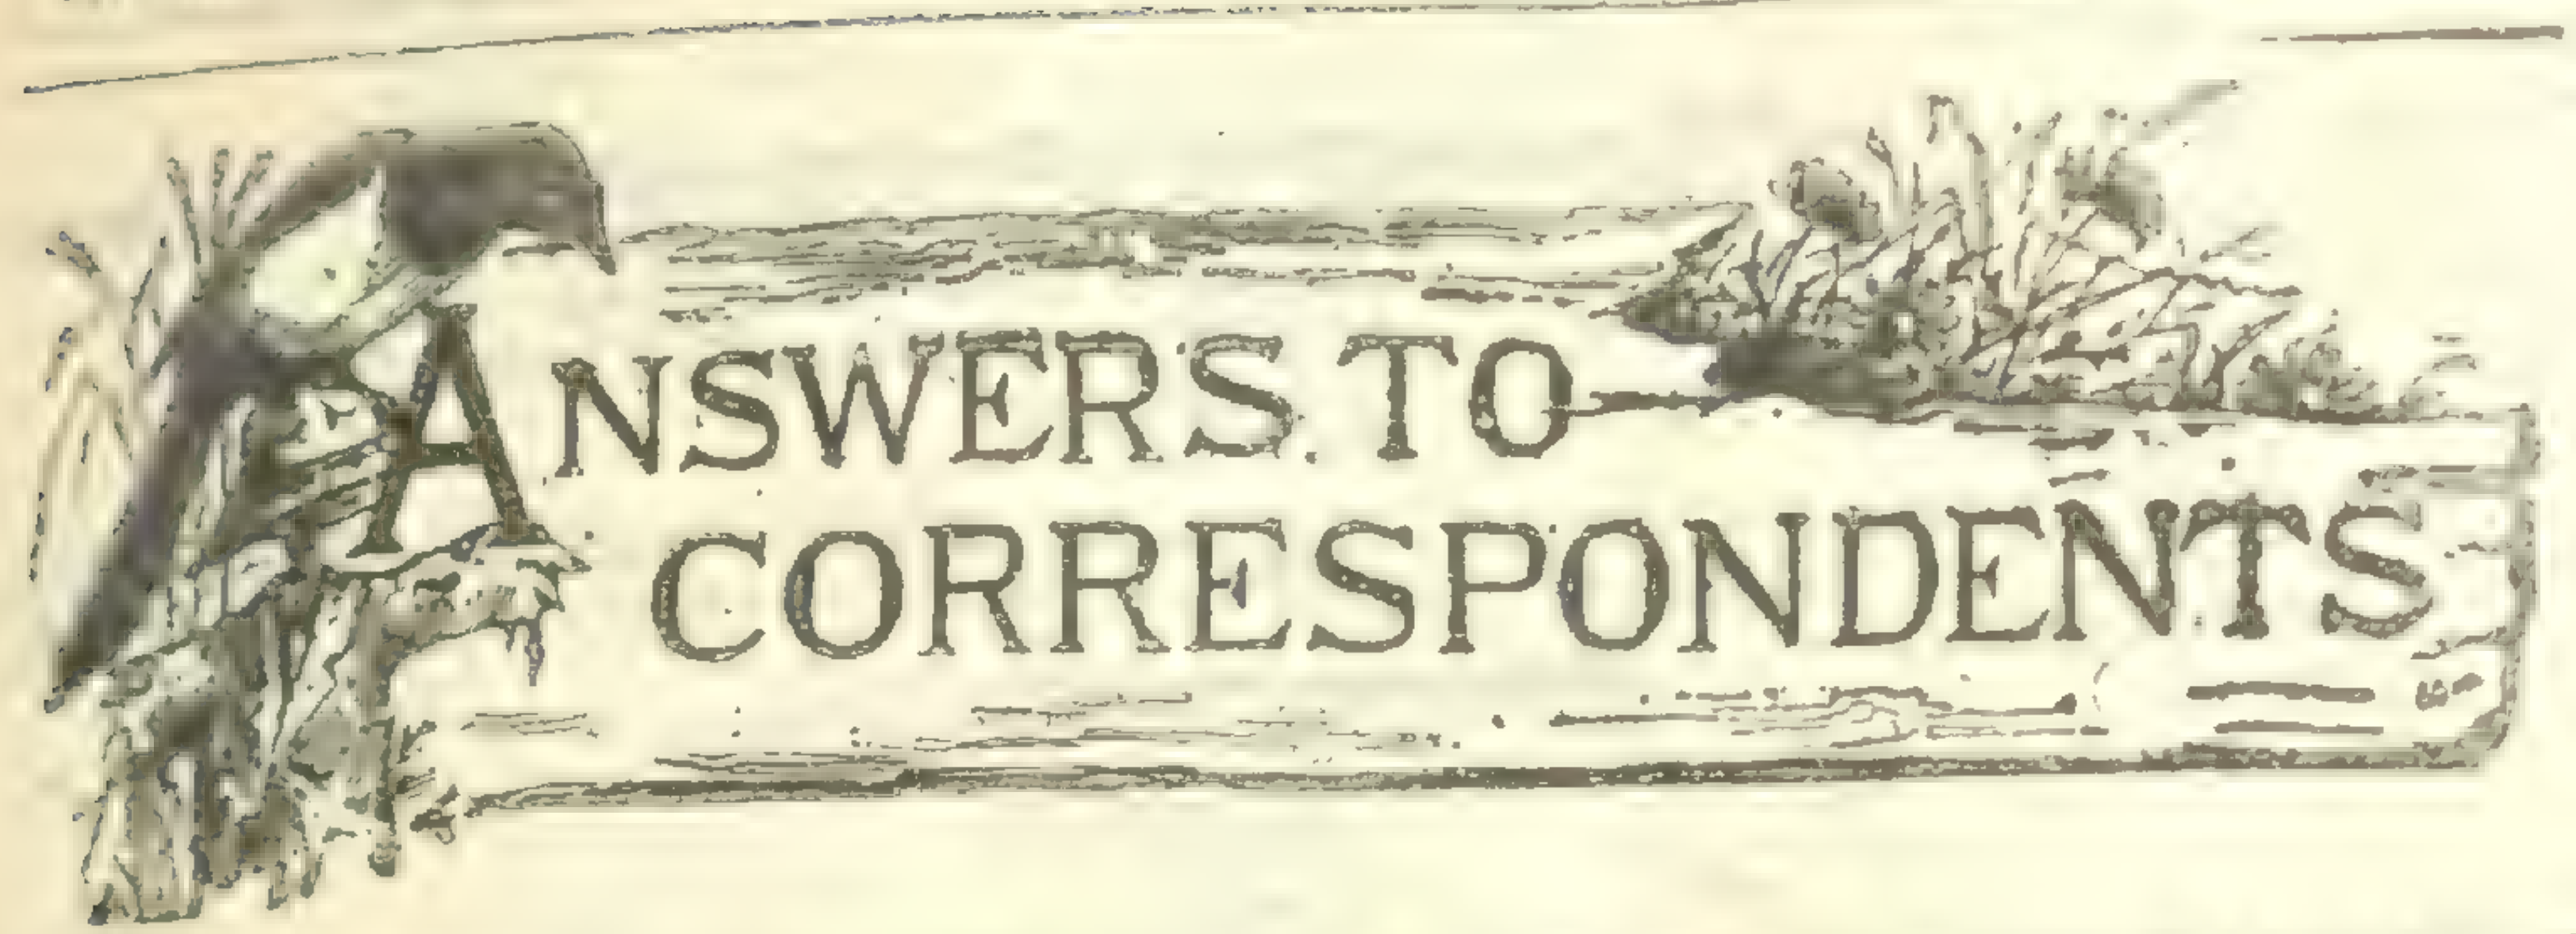
The third process is the one now in operation in the East. It was started at the Bengal plantations in 1885, and at Madras a year or two later. Now it is being adopted by the Dutch in Java. It is a satisfactory process, as it completely exhausts the bark, and is not very expensive to work. The bark is reduced to an almost impalpable powder by means of disintegrators driven at a high speed by water turbines. The powder is then mixed with water, caustic soda, and shale-oil; heated by steam-coils to about 160 degrees Fahrenheit, and kept constantly stirred by machinery for about an hour, when the stirring is stopped and the mixture allowed to rest quietly for an hour or two to let the oil—now containing the alkaloids—rise clear and bright to the top. The oil is then transferred to another vessel and thoroughly stirred up for a few minutes with sufficient dilute sulphuric acid to remove the whole of the alkaloids from it. After separation, by repose, the oil is drawn off for the next batch of bark, and the acidulated liquor, now containing the alkaloids in solution, is heated in steam-jacketed [illegible] neutralised with a weak solution of caustic soda or ammonia, and set aside to [illegible] and crystallise. To purify the crystals thus obtained they are collected, squeezed, redissolved in boiling water, digested for a few minutes with a little animal charcoal, filtered very hot, and allowed to cool, when the sulphate of quinine crystallises out quite white and clean.

Distribution of Quinine in India.

How to get the quinine to the very poorest in the outlying fever districts of Bengal at the lowest possible price, without burdening the public revenues, was an anxious question till the happy thought occurred to Sir Charles Elliott, late Lieutenant-Governor of Bengal, to make use of the Post Office Department [illegible] this purpose. He ordered the quinine to be put up in sealed packets of five [illegible] each, an ordinary dose, by jail labour, and sent to every outlying post office in Bengal for sale at the low price per packet of one pice, which is the lowest coin in ordinary circulation in Bengal, and of the value of about one farthing. Not only is a stock of these packets kept at all the post offices, but the postmen who visit the outlying hamlets have to carry them in their bags, and sell to any one who may ask for them. The postmasters and postmen get a small commission on the sale. A better or cheaper plan of distribution I cannot conceive, and the Italian Government have paid the Indian Government the compliment to adopt it for part of Italy.

Sulphate of quinine, quite equal in quality to the very best brands in the market, is now turned out by the Government at the Bengal factory alone, at the rate of about 1,000 lb. a month. Not many years ago, the annual quini[illegible] of the Government of Bengal was less than this monthly output. Madras [illegible] soon be turning out as much as Bengal, and perhaps more. So the Govern[illegible] can take credit for freely accomplishing the task they set themselves when introducing the cinchonas to India, as I trust I have proved to you without trying your patience over much.

Prevention of Potato Scab.—The scab of potatos may, [illegible] *Rural New Yorker*, in most cases, be prevented by soaking the seed in a [illegible] of corrosive sublimate. This remedy has been in use for several years, [illegible] been so generally successful that there can be no hesitation in [illegible] as thoroughly reliable. The chief objection to its use is its [illegible] nature. For this reason great caution should be used to prevent the [illegible] poisoning the food or drink of any animal, but at the strength here recom[illegible] it may be used to disinfect wounds. The solution should not come in [illegible] with metal, but should be prepared in earthenware or wooden vessels. To [illegible]pare the solution dissolve two ounces of corrosive sublimate in [illegible] fifteen gallons. In this solution soak the seed potatos for one [illegible] then cut and plant. After the seed has been soaked do not put it in boxes [illegible] receptacles in which scabby potatos have been kept. The scab fungus is [illegible] of living year after year in the soil, and, in some cases, the soil has become so [illegible] with it that, when potatos are grown therein, little benefit is derived from [illegible] the seed. In all ordinary cases, soaking the seed as directed will [illegible] from being scabby. Where the soil is badly infested, [illegible] secured good results by sprinkling sulphur in the open furrow at the [illegible] hundred pounds per acre. Professor Arthur has prevented the [illegible] the seed potatos for two hours in formalin, using eight ounces [illegible] water. This may be prepared in any kind of vessel, and has a [illegible] in that it is not poisonous. In purchasing the formalin, ask for the [illegible] formaldehyde gas, which is the name under which formalin is kept [illegible] chemists.



ANSWERS TO CORRESPONDENTS

Editorial communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Four-course System of Farming.—H. B. E., Buckingham: Briefly stated, the four-course system is as follows: First course—fallow crop, roots, such as potatos, mangold, swedes, and cabbage; second course—barley and oats; third course—clover, or clover with rye grass, beans, and peas; fourth course—wheat.

Nitrate of Soda for Asparagus.—A. W. P., Maidenhead: An excellent dressing for asparagus beds at the present time is half an ounce of nitrate of soda per square yard, to be followed by a similar dressing about the second week in May. Salt is valuable because it attracts and retains moisture about the roots of the asparagus. Soot, as a fertiliser for asparagus, is not used so much as it should be; it does not show to advantage, however, if the soil be at all chalky.

White Fly on Tomatos.—E. F. H., Barnstaple: As a rule this is not a very troublesome pest in gardens, though where large quantities of tomatos are grown it sometimes becomes a nuisance. It may be overcome by dipping or syringing the plants, using a solution of Calvert's carbolic soap at the rate of 2 oz. to each gallon of water. Dissolve the soap in hot water and then add the cold, using the solution in a lukewarm condition.

Cypripedium hybridum gigas.—J. C., Grantham: This cypripedium, of which you have lost the record, is the result of crossing C. Lawrenceanum with C. Harrisianum nigrum, and gained an award of merit from the Royal Horticultural Society on January 14, 1892. It was raised at Elstead, Godalming, where Mr. Bond is gardener to C. L. N. Ingram, Esq. Purplish crimson, white, and green are the prevailing colours. The dorsal sepal measures two and a half inches across.

Scorched Vine Leaves.—L. W. W., Slough: The vine foliage sent has been severely scorched by the bright sunlight of the past few days. Scorching, such as this, frequently occurs when a period of dull weather is followed by several days of bright sunshine. The damage is due to the lack of ventilation, or proper ventilation, for during dull weather some growers are too apt to coddle their vines, the leaf tissues are weakened and then are unable to stand the subsequent bright light and heat. When fine weather succeeds a period of dulness be careful to commence ventilating the vineries early in the day by opening the top ventilators a very little, increasing the opening as the day advances and the sun gains power. Vine growers need to be up early in the morning during March and April.

Pansy Bronze Prince.—L. F. H., Berwick: This crimson-bronze pansy was raised and sent out by Mr. H. Eckford, Wem, Salop; about four years ago it made its first appearance so far as we recollect.

Names of Plants.—M. I., Surbiton: 1, Pteris umbrosa; 2, P. serrulata; 3, Selaginella galeottiana; 4, S. amœna.

W. T. P. Chelmsford: Spiræa media, better known as S. confusa.

M. J. S. Exeter: 1, Cydonia japonica; 2, Sedum aizoideum; 3, Medicago lupulina; 4, Muscari botryoides; 5, Azalea mollis.

K. G. Luton: 1, Gesnera macrantha; 2, Clivia miniata; 3, a Tecoma, send when in flower; 4, Mahonia aquifolia; 5, Azalea amœna; 6, Acacia cordata.

B. S., Manchester: 1, Begonia albo-coccinea; 2, Lachenalia tricolor; 3, Semele androgyne; 4, Coccoloba platyclada.

L. M. A., Retford: 1, Oncidium sphacelatum; 2, Phaius grandifolius; 3, Dendrobium Bensoniæ; 4, Trichopilia suavis.

C. F., Bangor: 1, Vanda suavis.

F. P. S., Sunderland: 1, Megasea Stracheyi; 2, Acacia dealbata; 3, Thyrsacanthus rutilans; 4, Cyperus alternifolius variegatus.

G. A., Ealing: 1, Narcissus minimus; 2, Chionodoxa Luciliæ; 3, Narcissus Tazetta var.

MARKETS.

Covent Garden.

FOREIGN apples are scarce, but the best samples command high rates. For oranges and lemons there is a keen demand. Seakale and rhubarb are cheapening, but there is scarcely sufficient to meet the demand. Green vegetables are in moderate supply, and realise fair prices. Potato trade moderate, with a good demand for new.

FRUIT.—Nova Scotian apples, 15s. to 28s. per barrel; Californian Newtowns, 7s. to 12s. per case; bananas, 5s. to 10s. 6d. per bunch; pineapples, 2s. to 6s. each; English grapes, 1s. 9d. to 3s. 6d. per lb.; lemons, 6s. to 15s. per case; Canary tomatos, 1s. to 2s. per tray, 3s. 6d. to 5s. per case; Valencia oranges, 9s. to 10s. per case; Jaffa, 10s. to 12s. 6d. per box.

FLOWERS.—Arums, 3s. to 4s.; carnations, 1s. to 3s.; eucharis, 3s. to 4s.; gardenias, 2s. to 3s.; Lilium Harrisi, 3s. to 4s.; tea roses, 6d. to 1s.; pink roses, 4s. to 8s.; red roses, 3s. to 6s.; cattleyas, 6s. to 9s.; Odontoglossum crispum, 1s. 6d. to 4s.; tulips, 4d. to 9d.; and tuberoses, 1s. to 1s. 6d. per dozen blooms; Adiantum cuneatum, 4s. to 8s.; marguerites, 2s. to 4s.; narciss, various, 1s. 6d. to 3s.; Roman hyacinths, 4s. to 6s.; daffodils, 3s. to 6s.; mignonette, 2s. to 4s.; pelargoniums (scarlet), 4s. to 6s.; wallflowers, 4s. to 6s.; primroses, 9d. to 1s.; and violets, 9d. to 3s. 6d. per dozen bunches; azaleas, 6d. to 9d.; stephanotis, 4s. to 6s.; lily of the valley, 6d. to 1s. 6d.; and pelargoniums, 6d. to 9d. per dozen sprays; bouvardias, 6d. to 8d.; white lilac, 3s. to 4s. 6d. per bunch.

VEGETABLES.—Seakale, 12s. to 15s. per dozen punnets; celery, 8s. to 15s. per dozen rolls; English onions 7s. to 9s. per cwt.; Valencia 10s. to 12s. per case; cabbages and savoys, 3s. 6d. to 5s. 6d. per tally; green mint 4s. to 5s.; carrots, 3s. to 3s. 6d. per dozen bunches; French endive, 1s. 6d. to 1s. 9d.; lettuce, 9d. to 1s. 3d.; cos, 2s. to 2s. 6d.; cucumbers, 3s. to 6s. per dozen; asparagus, 2s. to 8s. per bundle; French beans (Madeira) 2s. 6d. to 3s. 6d. per basket; French green peas, 5d. to 6d. per packet; Kentish broccoli, 1s. to 2s. 6d. per dozen; Brussels sprouts, 1s. to 1s. 6d. per half-sieve; Canary new potatos, 10s. to 16s.; Malta, 10s. to 14s. per cwt.; mushrooms, 6s. to 8s. per doz. punnets.

A REVOLUTION in Chain-Driven LAWN MOWERS!

THE NEW PATENT

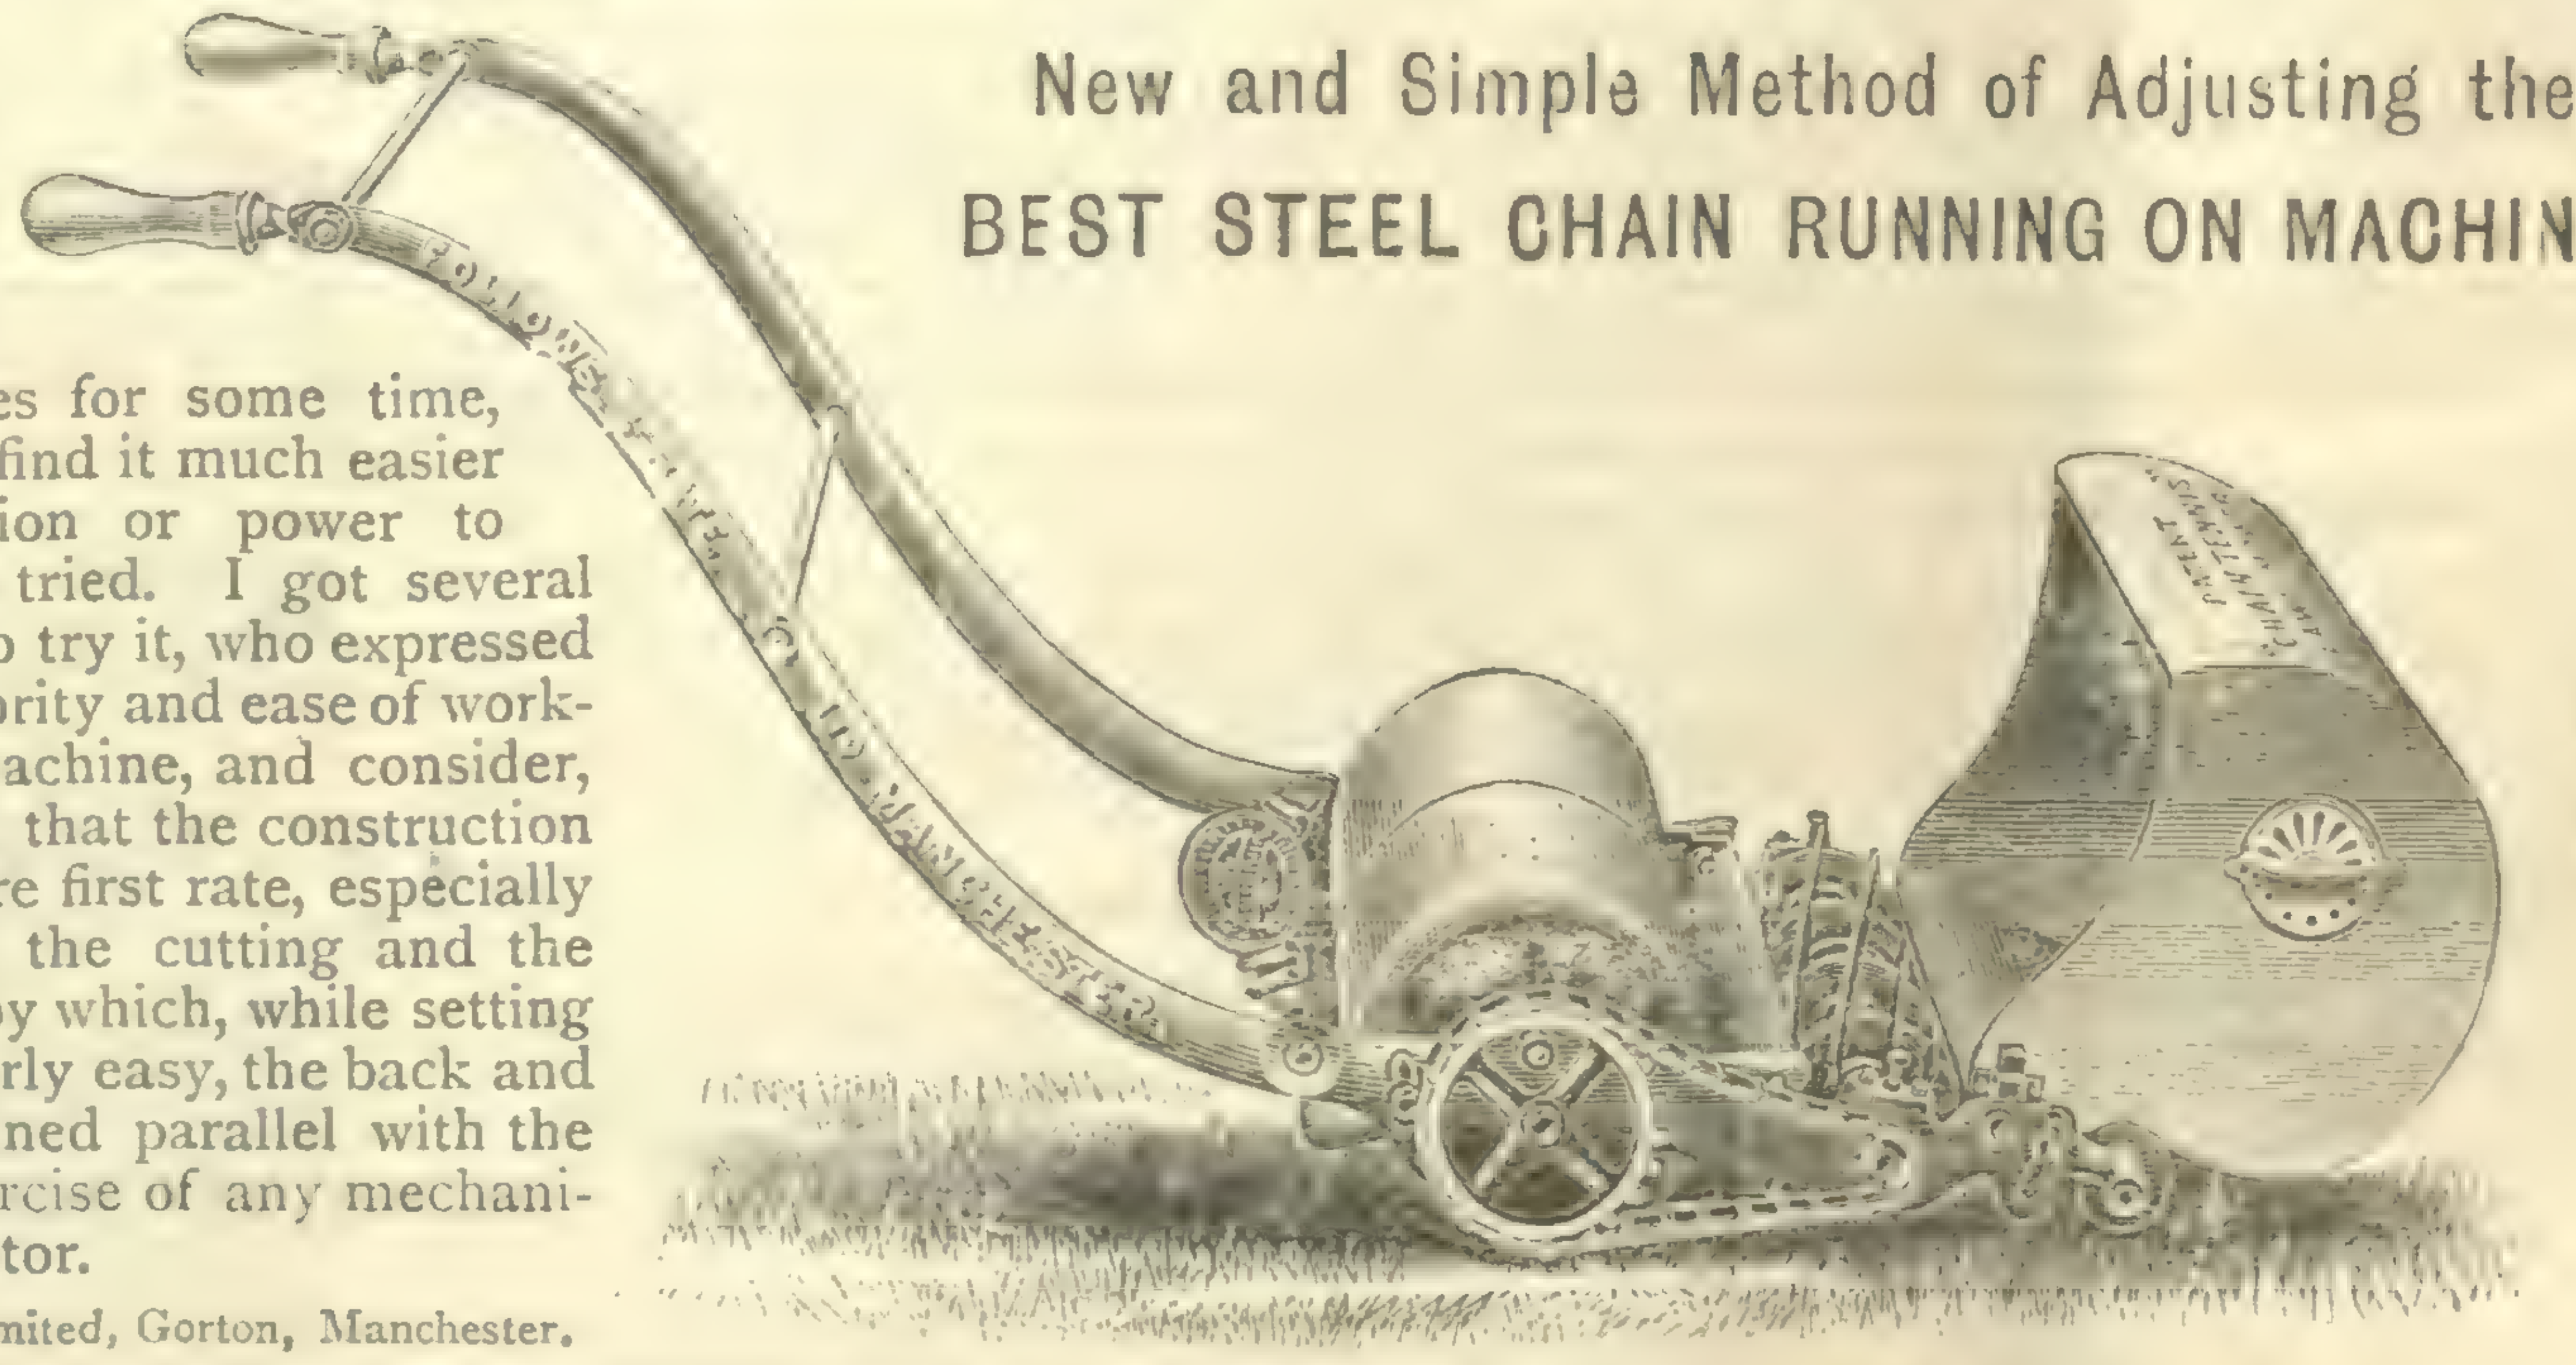
"CHAIN TENNIS" LAWN MOWER.

THE LATEST AND BEST CHAIN MACHINE. FITTED EQUAL TO A HIGH-GRADE BICYCLE.

TESTIMONIAL FROM
J. OWDEN O'BRIEN, Esq.,
M.I.M.E.
March 21st, 1898.

GENTLEMEN,—I have now had one of your 12 in. Chain-geared Lawn Mowing Machines for some time, and have personally tested it. I find it much easier to work, *i.e.*, takes less exertion or power to drive, than many others I have tried. I got several working or practical gardeners to try it, who expressed the same opinion as to its superiority and ease of working. I have also examined the machine, and consider, from a mechanical point of view, that the construction and arrangements of the parts are first rate, especially in reference to adjustment of the cutting and the tightening of the driving chain, by which, while setting of the parts is rendered particularly easy, the back and front rollers are always maintained parallel with the cutting cylinder without the exercise of any mechanical skill on the part of the operator.

To Messrs. FOLLOWS and BATE, Limited, Gorton, Manchester.



New and Simple Method of Adjusting the Chain and Cut.
BEST STEEL CHAIN RUNNING ON MACHINE-CUT WHEELS.

WEST'S
PATENT
IVORINE
PLANT LABELS
NAME TO BE WRITTEN ON WITH ORDINARY LEAD PENCIL OR PEN AND INK.

THE "IVORINE" WRITING DISC, Which is to be written upon, being made of a specially prepared substance, having the properties of real ivory, is imperishable, and does not corrode or eat away, like wood and metal labels; and being ivory-white, when written upon it shows to perfection. And also, as the writing is on the Ivorine itself it is permanent, though washable, and does not become unreadable, as is the case with all painted labels, as the paint gets old. It is for all purposes, and will last a century, either in a greenhouse or out in a garden, and not only is it always ready for use, and may be written on both sides. but the name when written in pencil may be easily rubbed off. and so used as many times as desired.

Samples and Lists of the West's Patent Specialities post free.

RICHARDS' PATENT, NO. 11,297.

G. H. RICHARDS, Manufacturer & Patentee,
124, SOUTHWARK ST., LONDON, S.E.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE.

Price **£3 10s.** per ton in bags. Lots under 10 cwt., **4s.** per cwt., 1 cwt. sample bag sent carriage paid to any station in England on receipt of P.O. for **5s.**

Extracts from 22nd annual collection of reports:—

NATIVE GUANO FOR POTATOS, VEGETABLES, &c.

C. H. TINDALL, Bardney: "Used for Potatos. Result very satisfactory; yield much above average. A splendid manure." G. WATTS and SONS, Bournemouth, report: "Good for general purposes. Grand for all Root Crops, Tomatos, and Cucumbers. Find it so cheap; and it does not exhaust the ground like other manures."

NATIVE GUANO FOR FRUIT, ROSES, TOMATOS, &c.

E. F. USHER, Sidcup: "Potatos and carrots, splendid crops; Peaches, Nectarines, &c., splendid. Should not like to be without it on any consideration" G. STONARD, Gardener to Sir A. T. Watson, Bart.: "Used for seven years for Peaches, Grapes, Tomatos, Cucumbers, Roses, and Chrysanthemums with excellent results."

Orders to the **Native Guano Co. (Limited),** 29, New Bridge Street, Blackfriars, London, where pamphlets of testimonials, &c., may be obtained. Agents Wanted.

THOMSON'S CELEBRATED MANURES for VINES and PLANTS. Result of long practical experience. Used by all successful growers. London agent, Mr. J. George, 14, Redgrave Road, Putney; Channel Islands, Mr. Parsons, Guernsey. Sole Makers, WM. THOMSON and SONS (LTD.), Clovenfords, Galashiels, N.B. Prices on application.

RAW CHINCHAS PERUVIAN GUANO, the genuine article, pure as imported—the highest quality—guaranteed analysis 10 per cent. Ammonia, 17 per cent. Phosphates, and 2 per cent. Potash. Unequalled for CHRYSANTHEMUMS, Roses, Tomatos, Celery, &c. Best fertiliser for use in gardens, greenhouses, nurseries, and market grounds. Be sure and ask for CHINCHAS Peruvian Guano, and see that you get it. OHLENDORFF'S GUANO GARDEN MANURE (made largely of Chinchas Guano) is specially recommended for plants requiring only mild manuring. Analysis guaranteed: 5 per cent. Ammonia, 24 per cent. Phosphate, and 3 per cent. Potash. These splendid fertilisers can be obtained of most nurserymen, seedsmen, and florists, all over the country, or direct from the importers of Chinchas Peruvian Guano; the Anglo Continental Guano Works, Branch Office, 30, Mark Lane, London. E.C., at following prices:—Raw Chinchas Peruvian Guano, 1 cwt. bags, 25s.; ½ cwt. bags, 14s.; ¼ cwt. bags, 8s. 6d.; 14 lb. bags, 5s.; 7 lb. bags, 3s.; 3 lb. tins, 1s. 6d.; and 1½ lb. tins, 1s. each. Ohlendorff's Guano Garden Manures:—1 cwt. bags, 16s.; ½ cwt, bags, 8s. 6d.; ¼ cwt. bags, 5s.; 14 lb. bags, 3s.; 7 lb. bags, 2s.; 3 lb. tins, 1s.; and 1½ lb. tins, 6d. each. Prices include cost of delivery from London, excepting that of the 1½ lb. tins Garden Manure.

GARDEN NETTINGS, Hothouse Shadings, Tiffany.—RIGBY, WAINWRIGHT, and Co., Manufacturers, Neptune Works, Manchester. Cotton Wools and Waddings.

BEAUTIFUL FLOWERS FOR PRESENT SOWING.

SUTTON'S SUPERB BEDDING ASTERS.
A splendid selection of dwarf varieties specially adapted for producing masses of colour in beds. The plants are uniform in habit and true to colour.
Scarlet, Delicate Rose, Bright Rose, Blue, Lilac, per packet, 1s.; White, per packet, 1s. 6d. Collection of the six colours, separate, 5s., post free.

SUTTON'S SUPERB BEDDING ASTERS.
Mr. R. Allan, gardener to J. Harrison, Esq., says:—"Your Bedding Asters have been admirable. The Rose, White, and Blue are true to a plant in colour, and not a quarter of an inch difference in height."

SUTTON'S SEEDS, GENUINE ONLY DIRECT FROM SUTTON AND SONS, THE QUEEN'S SEEDSMEN, READING.

NOTES OF THE WEEK.

SPRINGTIME.

Now that blustering March is well in the rear and the smiles and tears of April checker the face of the heavens with sunlit clouds, big dashes of clear blue, and here and there a vapoury veil of near or distant showers, the lover of his garden feels once again that life is indeed worth living, and the world a mine of marvels and beauties combined. No longer has he to be satisfied with the mere hints of coming things embodied in swelling buds and shoots which have to be sought for in precocious nooks and corners; the ground now is rampant with exuberant growth, the gaudy crocus blooms, first in the field, are now bedded in a spiky chevaux de frise of subsequent leafage; the broad glaucous green foliage of the tulips spreading wide, displays the coming blooms in many stages, the early Ducs already flaunting their brilliant chalices of scarlet and gold in the face of the sun, while the buds of their later and statelier relatives are still nestling in the hearts of the leaves in preparation to follow. Here is a clump of Crown Imperial pushing up so strongly and rapidly that one would expect at least a six-foot growth to result, though soon the circlets of malodorous blooms will cut the soaring short. The blue hepaticas, here and there, look like little bits of heaven's blue dropped from the sky above, and under the pretty blossoms the leaves are pushing vigorously to greet the sun as well. The crimson shoots of the pæonies glow in the sunbeams and sparkle ruddily with the rubies left by the latest shower. Among the alpine plants, one and all, saxifrage and sedum and all their kin are spreading their rosettes abroad; while primulas of all kinds, auriculas especially, seem literally bursting with vigorous life and energy after their long spell of winter rest. Shrubs of all descriptions are rapidly donning their leafy suits, and although the trees proper are tardier with their toilets, a very slight examination will show that the sap is busy at work and that the swelling buds will soon be shaking out their leafy plumes in response to the coaxing sun and showers, like all the rest. The hardier fruit trees, fortunately, are warily biding their time and keeping their precious freight of blossom well wrapped up until the night frosts grow less keen and perilous; and only the apricot and peach are foolish enough never to unlearn the lesson of their native land, and hence, year after year, spread their delicate blooms to the nipping airs of March in ever vain attempts at fruition. One of the most interesting studies indeed which we can take up in our garden strolls is that of adaptation of our floral pets to the seasons. Our native plants know quite well what they are about, and if of tender constitution, no blandishments will tempt them forth until they are fairly safe, while those of more precocious habits, laugh at the frost and snow, and take every opportunity between whiles of making growth and keeping up their character of firstlings of the spring. April indeed has phases of beauty which distinguish it from all other months of the year; its characteristic waywardness, a blend of blazing sun and warm rain, constitutes the very ideal of growing weather, good alike for roots, leaf, and blossom; and as a contrast to the bleak and blustering, keen and cutting months of winter and earlier spring, fills the heart of the true garden lover with an ineffable joy which the more generous floral gifts of summer fail, through satiety, to evoke.

WILD LIFE AT KEW.
